The effects of various treatments on fecal fat and nitrogen balance and on duodenal recovery of ingested pancreatic enzymes were evaluated in six patients with advanced pancreatic insufficiency to provide a rational basis for pancreatic enzyme replacement therapy after a solid test meal. The combination of cimetidine and pancreatin (300 mg and 2.5 g, resp., p.o.) produced significantly higher postprandial duodenal recoveries and concentrations of trypsin and lipase ($p<0.05$). Steatorrhea was reduced in all patients and abolished in four of the six. In the dosages used, neither enteric-coated enzymes nor supplemental neutralizing antacids were more effective than pancreatin alone in decreasing steatorrhea or improving duodenal enzyme delivery. Cimetidine may be a useful adjunct to p.o. pancreatic extract therapy in some patients with severe pancreatic insufficiency who fail to respond to pancreatic enzyme replacement alone. No side-effects attributable to cimetidine were noted.

2306 REGIONAL PANCREATECTOMY: EN BLOC PANCREATIC, PORTAL VEIN AND LYMPH NODE RESECTION. (Eng.) Fortner, J. G.; Kim, D. K.; Cubilla, A.; Turnbull, A.; Pahnke, L. D.; Shils, M. E. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021). *Ann. Surg.* 186(1):42-50; 1977.

Experience with 18 patients who had a regional pancreatectomy is presented. The pancreatic segment of portal vein was excised with the en bloc total pancreatectomy and regional lymph node dissection in all patients. Venous repair was by end-to-end anastomosis without a graft. Five patients also had various arterial resections and reconstructions. Sixteen of the 18 had been explored and deemed nonresectable in other institutions. This operation has doubled the resectability rate in the authors' institution. The 30-day operative mortality rate was 16.6%. Actuarial survival is 62% at 1 yr compared with a 36% 1-yr survival rate for patients undergoing pancreaticoduodenectomy for less advanced cancer in previous years. A more valid comparison would be between those who had a palliative procedure, since most patients in the present series were initially considered unresectable. One-year survival for these patients was 22%. The quality of life was good for most patients.

2307 ANALYSIS OF PANCREATIC FUNCTION THROUGH FECAL CHYMOTRYPSIN DETERMINATION AND SECRETIN-PANCREOZYMIN TEST: A COMPARATIVE STUDY. (Ger.) Tympner, F.; Reiner, T.; Domschke, W. (Med. Univ.-Klinik, Krankenhausstrasse 12, 852 Erlangen, W. Germany). *Fortschr. Med.* 95(27): 1711-1714; 1977.

PANCREAS

Pancreatitis

2311 MECHANISM AND SPECIFICITY OF INCREASED AMYLASE/CREATININE CLEARANCE RATIO IN PANCREATITIS. (Eng.) Marten, A.; Beales, D.; Elias, E. (Royal Free Hosp., London, England). *Gut* 18(9):703-708; 1977.

The amylase/creatinine clearance ratio (Cam/Ccr ratio) was determined in 89 controls, 13 patients with acute pancreatitis, 18 patients with choledocholithiasis, 14 diabetics, 19 alcoholics with liver disease, 30 patients with chronic pancreatitis, 3 patients with peptic ulcer, 12 patients with primary biliary cirrhosis, 13 patients with pancreatic carcinoma, and 30 patients with chronic renal failure to test the specificity of the Cam/Ccr ratio and to observe the relationship of plasma glucagon to renal amylase clearance. In the 87 hospitalized control patients without pancreatic disease, the Cam/Ccr ratio was 3.02 ± 0.69. The ratio was above the normal range in all patients with acute pancreatitis but was normal in those with chronic pancreatitis and carcinoma of the pancreas. In 18 patients with cholelithiasis, an increased ratio distinguished those with pancreatitis, as assessed independently during laparotomy, from those with a macroscopically normal pancreas. Raised Cam/Ccr ratios were also found in diabetics with ketoacidosis and in three patients with fulminant alcoholic liver disease. Although a positive correlation was found between the Cam/Ccr ratio and serum creatinine concentration, abnormally high ratios did not occur in the 30 patients with chronic renal failure. A significant increase in Cam/Ccr ratios was produced in six healthy volunteers by the i.v. injection of glucagon. However, it is unlikely that hyperglucagonemia alone accounts for the increased Cam/Ccr ratio seen in acute pancreatitis, as no correlation was found between the clearance ratio and the plasma glucagon concentration in a series of patients. In two other patients in whom excess circulating pancreatic polypeptide was detected, the Cam/Ccr ratio was normal. It is concluded that, in view of the sensitivity and relative specificity of finding an increased Cam/Ccr ratio in acute pancreatitis, its determination should be valuable clinically, especially in those cases of hyperamylasemia where the cause is in doubt. It is unlikely that either glucagon or pancreatic polypeptide is a major factor in the production of the increased Cam/Ccr ratio.

LIVER AND BILIARY TRACT

2326 MICROCALORIMETRIC MEASUREMENTS OF HEAT PRODUCTION IN ERYTHROCYTES OF PATIENTS WITH LIVER DISEASES. (Eng.) Monti, M. (Univ. Hosp., S-221 85 Lund, Sweden). *Scand. J. Haematol.* 19(3):313-318; 1977.

RBC metabolic activity was investigated in 12 patients with severe liver disease. Measurements of RBC heat production and glucose consumption were made *in vitro* with and without stimulation of the pentose phosphate pathway with methylene blue. The RBC resting heat effect value was 25% higher than normal ($p<0.005$). A normal value was obtained when heat effect was measured under maximal stimulation with 10^{-4} M methylene blue. Glucose consumption was normal, both in unstimulated and methylene blue-stimulated RBC. The results do not support the hypothesis that hemolytic anemia in patients with liver disease is related to decreased activity of the pentose phosphate pathway.

2327 DIFFUSE INTRAVASCULAR COAGULATION IN LIVER DISEASE? (Eng.) Straub, P. W. (Inselspital, Berne, Switzerland). *Semin. Thromb. Hemostas.* 4(1):29-39; 1977.

Arguments for the role of diffuse intravascular coagulation (DIC) in liver diseases are critically reviewed. The following signs of DIC are discussed: the presence of microthrombi, hypofibrinogenemia and decreases in factors V and VIII, thrombocytopenia, the accelerated disappearance of plasma fibrinogen, increases in circulating FDP, the presence of fibrinogen-fibrin complexes, and the reversal of laboratory abnormalities after heparin therapy. In general, although some degree of activation of coagulation is probably present in a condition associated with tissue necrosis, the role that it plays in the hemostatic failure of patients with liver diseases appears to be far from established. In the presence of decreased fibrinogen synthesis, even discrete DIC could result in impressive finding, apt to be misinterpreted in their significance. Findings compatible with a diagnosis of DIC, and subject to the same criticism, have also reported various severe acute liver diseases other than cirrhosis. Therapy is discussed with reference to the current knowledge concerning the pathophysiology of the coagulation defect in liver diseases.

2328 COAGULATION ABNORMALITIES IN LIVER DISEASE. (Eng.) Lechner, K.; Niessner, H.; Thaler, E. (First Dept. Medicine, Univ. Vienna, Vienna, Austria). *Semin. Thromb. Hemostas.* 4(1):40-56; 1977.

Recent data relating to coagulation abnormalities in liver disease are summarized; pathogenetic factors responsible for these abnormalities are discussed; and the role of functional and immunologic clotting tests for the evaluation of liver function and the differential diagnosis and prognosis of liver disease is defined. In the majority of patients with liver disease, the blood levels of the vitamin K-dependent clotting factors (factors II, VII, IX, and X) are reduced primarily because of the decreased capacity of the liver to synthesize proteins. The activity of antithrombin III is also decreased in patients with acute and chronic liver disease, and a prolonged thrombin time is often observed. The degree of reduction of clotting factors II, V, VII, and X, and of antithrombin III correlates fairly well with the extent of liver damage and can be used as a guide to prognosis, provided that other mechanisms that may influence the blood levels are carefully considered. Clotting factor assays have only a limited value for the differential diagnosis of liver disease, however. Specific blood coagulation changes in the following liver diseases are discussed: acute liver disease, liver cirrhosis, chronic hepatitis, biliary cirrhosis and obstructive jaundice, Dubin-Johnson syndrome, Gilbert syndrome, primary hepatocellular carcinoma, and metastatic cancer of the liver.

2329 THE LIVER IN SARCOIDOSIS. (Eng.) Lehmuskallio, E.; Hannuksela, M.; Halme, H. (Univ. Central Hosp., Helsinki, Finland). *Acta Med. Scand.* 202(4):289-293; 1977.

The results of liver function tests were studied in 325 Finnish patients with sarcoidosis and in 132 patients with nonsarcoid erythema nodosum, and needle biopsy specimens of the liver were examined in 121 sarcoidosis patients. Granulomas compatible with sarcoidosis were seen in 24% of the 121 biopsied cases. Liver function tests (serum alkaline phosphatase, serum alanine aminotransferase, serum aspartate aminotransferase, and BSP clearance test) were abnormal, especially in patients with extensive erythema nodosum, but there was no correlation with the disease responsible for the eruption. Serum alanine aminotransferase was markedly increased in 3 of 61 cases examined; all of these patients had erythema nodosum. Among 310 cases examined, 1.3% had high alkaline phosphatase levels, all of whom had sarcoidosis. BSP excretion was abnormal in 8% of the patients examined. Hepatic granulomas were found more often in patients with sarcoid changes in the lung parenchyma than in those with bilateral hilar adenitis only (14/46 cases versus 10/64 cases). There were no other definite correlations between hepatic granulomas and other clinical and laboratory findings. The incidence of pathological results in this study was clearly lower than that in the United States, thus reflecting a good prognosis of sarcoidosis in the Scandinavian countries.

2330 CHRONIC LIVER DYSFUNCTION IN MULTITRANSFUSED HEMOPHILIACS. (Eng.) Hasiba, U. W.; Spero, J. A.; Lewis, J. H. (Central Blood Bank Pittsburgh, 812 Fifth Ave., Pittsburgh, PA 15219). *Transfusion* 17(5):490-494; 1977.

The potential adverse effects of long-term exposure to multiple lots of pooled fractions was evaluated by determining SGPT and SGOT levels and serum hepatitis B surface antigen (HBsAg) and antibody to HBsAg (anti-HBs) during a 3-yr period in 118 patients with factor VIII or factor IX deficiency. The 107 HBsAg-negative patients were divided into four groups according to their mode of therapy. Persistently abnormal transaminase values were present in 51% of patients with a large exposure to factor VIII concentrates, in 43% with a small factor VIII exposure, and in 37% exposed to prothrombin complexes. This was contrasted with abnormalities in 8% of patients treated only with cryoprecipitate. The incidence and degree of serum transaminase abnormality appeared to be independent of a past history of jaundice. All patients without persistent antigenemia who had been treated with pooled plasma products showed antibodies to HBsAg. High titer anti-HBs prior to initial fraction therapy appeared to be protective against jaundice. The 11 patients with persistent antigenemia had significantly higher transaminase levels than the HBsAg-negative group.

2331 LIVER DYSFUNCTION IN PATIENTS WITH HEMOPHILIA A, B, AND VON WILLEBRAND'S DISEASE. (Eng.) Hilgartner, M. W.; Giardina, P. (Cornell Univ. Medical Coll.-New York Hosp., 525 E. 68th St., New York, NY 10021). *Transfusion* 17(5):495-499; 1977.

The incidence of liver disease was determined in 95 patients with hemophilia A or B, or von Willebrand's disease, who were followed over a 3-yr period. Half the patients were treated episodically, and half received additional prophylactic treatment. Fifty-five per cent had significantly elevated SGOT and SGPT levels, and had biochemical evidence of chronic active liver disease. Two percent had subacute and active cirrhosis. There was an annual attack rate of hepatitis B of 3.5%, and hepatitis B antibody titers were present in 84%. Asymptomatic liver disease in patients with hemophilia requires close monitoring to determine the clinical significance.

2332 CONTRACEPTIVE STEROIDS AND LIVER LESIONS. (Eng.) Garcia, C. R.; Gordon, J.; Drill, V. A. (Univ. Pennsylvania Hosp., Philadelphia, PA 19104). *J. Toxicol. Environ. Health* 3(1/2):197-206; 1977.

Factors concerning the possible untoward effect of oral contraceptives on the liver are reviewed. During the past 10 yr, an increasing number of cases of hepatic adenomas and related lesions has been reported in women using these contraceptives. Such lesions occur only rarely, but it is the rarity itself that makes it difficult to evaluate the role of the contraceptive steroids. The enormity of the denominator in contraceptive steroid usage is so unwieldy that mechanisms to measure accurately the difference in an extremely small numerator are still plaguing the epidemiologist, who at best can supply only estimates. Oral contraceptives do not significantly alter liver function tests in experimental animals, although women receiving the steroids may show a small degree of BSP retention similar to that occurring during pregnancy. Benign cholestatic jaundice may occur in patients taking the pill, although it is now recognized that this jaundice is similar to the benign cholestatic jaundice of pregnancy and that it occurs primarily in women with a history of the latter.

2333 SYSTEMIC AND REGIONAL TREATMENT OF PRIMARY CARCINOMA OF THE LIVER. (Eng.) Lee, Y. T. N. (Univ. Southern California Medical Center, Los Angeles, CA 90033). *Cancer Treat. Rev.* 4(3):195-212; 1977.

Therapy for primary hepatic carcinoma is reviewed, with particular emphasis on the results of each type of therapy. The median survival after diagnosis for symptomatically treated patients is less han 4 months. Surgical resection is the treatment f choice. The reported resectability rate was -30%, and the operative mortality rate 12.5-34%. lthough the majority of cases die with recurrent isease, patients whose lesion can be resected ave the highest 5-yr survival rate (10-15%). Radioherapy has been shown to be of limited benefit or primary carcinoma of the liver. Although chemoherapy in the past produced a low response rate nd did not prolong survival times, in a recent tudy, 7 of 19 patients had objective response to ombinations of 5-fluorouracil (5-FU) and bischlorothyl-nitrosourea (BCNU), and 3 patients were in omplete remission for 3, 4 and 6 yr, resp. In nother study, all 11 patients responded to adriaycin (median survival=8 months), with 3 exhibiting omplete tumor regression and surviving 8, 9, and 3 months, resp. Several reports showed that the ntra-arterial infusion of chemotherapeutic agents 5-FU, fluorodeoxyuridine, methotrexate, and mitoycin) can cause response in 50-75% of the cases, nd prolong survival over untreated patients or atients receiving other routes of chemotherapy. eliberate ligation of the hepatic artery has been sed as treatment of primary tumors of the liver. xcluding patients with cirrhosis, massive involveent of the liver, and far-advanced hepatic decomensation, the overall operative mortality associated with hepatic artery ligation is about 19%, ith 4% directly attributable to ligation of the rtery. Several investigators have administered hemotherapeutic agents either to branches of the ortal vein or to the distal hepatic artery to revent tumor regrowth. However, there is no definite evidence that hepatic artery ligation, with r without added infusion chemotherapy to the iver, gives better response and/or survival results than infusion chemotherapy to the hepatic rtery alone. Other therapeutic approaches such s infusion chemotherapy via the portal vein, ligation of portal vein branches, and liver translantation have not shown definite benefit. On he other hand, two cases of spontaneous regression f hepatoma and three cases of documented cure fter 5-FU or 5-FU-BCNU combination chemotherapy have een reported. For nonresectable lesions of heatic carcinoma, regional and systemic chemotheraeutic treatment is available. With the availaility of adriamycin and newer combinations of ffective agents, the outlook for such patients ay be greatly improved.

2334 GRANULOMATOUS LIVER DISEASE AND GIANT CELL ARTERITIS. CASE REPORT AND LITERAURE REVIEW. (Eng.) Litwack, K. D.; Bohan, A.; ilverman, L. (Hoag Memorial Hosp., Newport Beach, A 92663). *J. Rheumatol.* 4(3):307-312; 1977.

he case of a 64-yr-old woman with granulomatous iver disease associated with the polymyalgia heumatica-giant cell arteritis syndrome is preented. Treatment with prednisone (45 mg/day) reulted in prompt improvement in both the polymyalgia heumatica-giant cell arteritis syndrome, as well s the tests of liver function. Polymyalgia rheuatica and giant cell arteritis may involve the liver and should be included in the differential diagnosis of granulomatous liver disease.

2335 SERUM, CEREBROSPINAL FLUID, AND BRAIN LEVELS OF BILE ACIDS IN PATIENTS WITH FULMINANT HEPATIC FAILURE. (Eng.) Bron, B.; Waldram, R.; Silk, D. B. A.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, England). *Gut* 18(9):692-696; 1977.

To investigate whether the known toxic effects of bile salts are involved in the pathogenesis of cerebral edema in fulminant hepatic failure (FHF), bile acid levels were measured in the sera, cerebrospinal fluid (CSF), and brain tissue of 10 patients immediately after death from FHF. Serum bile acids in FHF were predominantly conjugated, and total bile acid levels were higher in all 10 patients than in normal controls (85.9 ± 8.4 compared with 5.7 ± 0.4 nmol/ml, $p<0.001$). Small but significant amounts of bile acids were detected in CSF (range 1.2-5.3 nmol total bile acid/ml) and brain biopsies (1.0-18.8 nmol/g wet weight) of FHF patients, whereas none could be detected in CSF and brain biopsies of patients dying without evidence of liver disease. There was no relationship between serum, CSF, or brain levels of bile acids and duration of coma, or presence of cerebral edema found in five FHF patients at necropsy. However, serum bile acid levels were similar in FHF to those found in chronic liver disease without encephalopathy and lower than those found to inhibit brain respiration *in vitro*. A primary role for these compounds in the pathogenesis of coma in FHF therefore seems unlikely.

2336 RECURRENT HEMATOBILIA AFTER PERCUTANEOUS LIVER BIOPSY. (Ger.) Fengler, J. D.; Baumgarten, R. (Infektionsklinik des Stadtischen Krankenhauses Berlin-Prenzlauer Berg, Nordmarkstr., 15, DDR-1055 Berlin, E. Germany). *Dtsch. Gesundheitsw.* 32(5):213-215; 1977.

Granulomatous hepatitis (GH) is a disease with chronic and hidden course, with various intensities of clinical symptoms and morphological changes, mainly in the form of granulomas situated in liver lobules and portal spaces. Most frequently, GH is caused by such chronic infections as tuberculosis, brucellosis, tularemia, Q fever, syphilis, deep mycosis, and also by sarcoidosis and Hodgkin's disease. Intensity of nodular infiltrations in tuberculosis depends on the kind, localization, and intensity of the disease. Similar granulomatous changes are observed in active brucellosis, especially caused by *Brucella abortus bovis*. Nodular infiltrations of the liver with a tendency to necrosis and caseation appear during the acute period of tularemia. Hepatosplenomegaly and hepatic malfunction in Q fever are also accompanied by granulomatous infiltrations. Similar changes occur in mononucleosis and mycosis, and especially in actinomycosis, when macroscopic nodules and abscesses may occur in the liver. GH is very often caused by sarcoidosis in which granulomatous infiltrations in liver are found in 60% of the cases. Polymorphic infiltrations occur in 70% of the cases in Hodgkin's disease. GH can be also caused by several chemical and pharmacological agents. It was observed in berylliosis, silicoidosis, poisoning by copper-containing pesticides, drug hypersensitivity, and in some autoimmune diseases. It is not known whether liver granulomas are caused by action of exogenous agents or autoimmunization. Even though clinical symptoms of GH are different and nonspecific, detailed studies based on biopsies should clarify the mechanism of reaction of liver tissue to the pathogenic agents.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

2372 HBsAg, CHRONIC LYMPHOPROLIFERATIVE DISORDERS, AND CIRRHOSIS OF LIVER. (Eng.) Heimann, R.; Ray, M. B.; Desmet, V. J. (Dept. Pathology, Institut Jules Bordet, Univ. Brussels, B. 1000 Brussels, Belgium). *J. Clin. Pathol.* 30(9): 817-821; 1977.

The incidence of hepatitis B surface antigen (HBsAg) was studied in 23 necropsy cases of chronic lymphoproliferative disorders to clarify the previously reported high incidence of cirrhosis in such disorders. The type of lymphoma was reviewed in the light of the new functional classifications of non-Hodgkin malignant lymphomas introduced by Lennert and Lukes. The presence of HBsAg in the liver was investigated by the indirect immunofluorescence technique. Eleven cases showed plasmocytoid features and were considered to be immunocytomas. Seven cases showed liver cirrhosis; six of them belonged to the immunocytoma group. Four cases were HBsAg-positive. Three of them were found among the group combining cirrhosis and immunocytoma. They presented the abundant nodular distribution of HBsAg typical of inactive cirrhosis. A parallel is drawn between the often reported association of Waldenstrom's syndrome and cirrhosis and the association of immunocytoma and cirrhosis observed in this study. The analogy is further justified since most of the lymphomas associated with Waldenstrom's syndrome happen to be immunocytomas. Therefore the association between hepatitis B virus infection and cirrhosis on the one hand and chronic lymphoproliferative disorders on the other may not be purely coincidental. A chronic antigenic stimulus such as persisting HBsAg could trigger the proliferation of a malignant lymphoid clone.

LIVER AND BILIARY TRACT

Chronic Hepatitis

2412 CHRONIC ACTIVE HEPATITIS AND PULMONARY HYPERTENSION. (Eng.) Cryer, P. E.; Kissane, J. M.; Pierce, J.; Biello, D.; Kuhn, C., III; Lander, J.; *et al.* (Washington Univ. Sch. Medicine, St. Louis, MO). *Am. J. Med.* 63(4):604-613; 1977.

A 46-yr-old woman suffered cardiopulmonary arrest and died shortly after a second hospitalization for shortness of breath. She had been hospitalized 4 yr earlier for what was diagnosed as viral hepatitis, but had an apparently uneventful recovery. She had been taking a phenothiazine preparation, which she continued to take throughout the next year. Chronic active hepatitis, cirrhosis, and slight cardiomegaly were noted when she was rehospitalized 2.5 yr later for extreme shortness of breath. A cushingoid appearance developed after treatment with prednisone (20 mg/day), and the dosage was decreased to 5 mg/day. The diagnosis of chronic active hepatitis and cirrhosis was reconfirmed when the patient was rehospitalized 1 yr later. Pulmonary hypertension was also confirmed, and she appeared not to have a cardiomyopathy. The final anatomic diagnosis was chronic active hepatitis with cirrhosis of the liver, mild glomerulonephritis, chronic pancreatitis, primary pulmonary hypertension, and a small pulmonary thromboembolus.

LIVER AND BILIARY TRACT

Cirrhosis

2430 LIVER IMAGING DURING RETICULOENDOTHELIAL FAILURE. (Eng.) Antar, M. A.; Sziklas, J. J.; Spencer, R. P. (Veterans Admin Hosp., Newington, CT). *Clin. Nucl. Med.* 2(9):293-295; 1977.

The cases of two men with hepatic cirrhosis in whom the liver could not be visualized by means of i.v. administered ^{99m}Tc-sulfur colloid are described. There was thus hepatic "reticuloendothelial failure." In one case, the liver could be imaged following the i.v. administration of ^{67}Ga-citrate. In the second case, the liver retained some ability to accumulate ^{131}I-rose bengal. These cases emphasize the fact that one class of radiopharmaceuticals may be accumulated while another is not.

2431 PRESYMPTOMATIC PRIMARY BILIARY CIRRHOSIS. (Eng.) Hanik, L.; Eriksson, S. (Malmo

General Hosp., Malmo, Sweden). *Acta Med. Scand.* 202(4):277-281; 1977.

Clinical, laboratory, and follow-up results in 13 patients with asymptomatic primary biliary cirrhosis (PBC) collected during the last 10 yr in one hospital that serves a population of 250,000 inhabitants are presented. The mean observation time was 5.5 yr. Seventy-seven percent of these patients were asymptomatic at the time of diagnosis. Characteristic laboratory features in these asymptomatic patients were high alkaline phosphatase and glutamyl transpeptidase levels and very high levels of polyclonal IgM. The ESR was often increased. Signs of active cell destruction were slight, and functioning cell mass was well preserved. High titers of mitochondrial antibodies were consistently present. Needle biopsy was seldom sufficient for diagnosis but permitted staging of the disease. There was no correlation between clinical features and histological evolution stage. Compared with a preceding 10-yr period, the incidence of PBC has risen threefold. This increase can be fully explained by the extended use of laboratory facilities, resulting in the detection of PBC in asymptomatic patients.

2432 AN IMPROVED METHOD FOR MEASURING BLOOD MERCAPTANS.

(Eng.) Doizaki, W. M.; Zieve, L. (Minneapolis Veterans Hosp., Univ. Minnesota, Minneapolis, MN 55417). *J. Lab. Clin. Med.* 90(5):849-855; 1977.

An improved method for measuring blood methanethiol (MT), in which zinc was used as a reducing agent and a more sensitive gas chromatograph was employed, is described. The method can be used for measuring covalently bound MT that was not previously detected and permits determinations in patients for the first time. The average normal whole-blood MT in rat blood was 200 ± 42 pmol/ml and in human blood 229 ± 29 pmol/ml. Eleven rats in experimental hepatic coma following acute massive hepatic necrosis had blood levels 4 to 18 times the average normal, and seven cirrhotic patients with hepatic encephalopathy or coma had blood levels 4 to 5 times the average normal.

2433 IN VITRO CELL-MEDIATED CYTOTOXICITY IN PRIMARY BILIARY CIRRHOSIS AND CHRONIC HEPATITIS: DYSFUNCTION OF SPONTANEOUS CELL-MEDIATED CYTOTOXICITY IN PRIMARY BILIARY CIRRHOSIS.

(Eng.) Vierling, J. M.; Nelson, D. L.; Strober, W.; Bundy, B. M.; Jones, E. A. (Natl. Inst. Health, Bethesda, MD 20014). *J. Clin. Invest.* 60(5):1116-1128; 1977.

The *in vitro* cytotoxic function and target cell specificity of peripheral blood lymphocytes from 10 patients with primary biliary cirrhosis and 9 with hepatitis B surface antigen-negative chronic hepatitis were investigated using ^{51}Cr-labeled human Chang and EL-4 mouse sarcoma cell targets in assays of spontaneous cell-mediated cytotoxicity (SCMC) and mitogen-induced cellular cytotoxicity (MICC). In addition, antibody-dependent cellular cytotoxicity (ADCC) against Chang cells was assessed. At an effector-to-target cell ratio of 100:1, the mean SCMC against Chang cells was much less in patients with primary biliary cirrhosis than that in either the 11 healthy controls ($p<0.001$) or the patients with chronic hepatitis ($p<0.005$), whereas the value for patients with chronic hepatitis did not differ significantly from that of the controls. The mean SCMC against EL-4 mouse sarcoma cells was also less in patients with primary biliary cirrhosis than in the controls ($p<0.005$), whereas the value for chronic hepatitis was not significantly different from that of the controls or patients with primary biliary cirrhosis. In contrast, MICC against both targets and ADCC against Chang cells were similar for each group. Comparison of SCMC and MICC against both target cells, measured simultaneously, showed similar cytotoxic potential against both target cells for each group. Effector cells capable of mediating cytotoxicity in each assay were defined by testing the cytotoxic function of lymphocyte subpopulations isolated from two representative patients with each disease using immunoabsorbent affinity chromatography and crystallizable fragment (Fc) receptor binding to antigen-antibody complexes. In both primary biliary cirrhosis and chronic hepatitis, SCMC and ADCC were mediated by a subpopulation of lymphocytes that lack surface immunoglobulin (sIg-) and bear Fc receptors (Fc+). In contrast, MICC was mediated by sIg-cells, which lack Fc receptos. Lymphocytes bearing sIg were not cytotoxic in any assay. These results establish that there is a difference in cytotoxic function in primary biliary cirrhosis and chronic hepatitis by defining the presence of a defect in spontaneous cytotoxic function of sIg-, Fc+ lymphocytes against Chang cells in primary biliary cirrhosis.

2434 MACROMOLECULAR LACTATE DEHYDROGENASE LINKED TO SERUM IgG OF A PATIENT WITH LIVER CIRRHOSIS.

(Eng.) Hayashi, S.; Noma, K.; Kobayashi, R.; Kosaka, K. (Okayama Univ. Medical Sch., Okayama 700, Japan). *Acta Med. Okayama* 30 (2):75-86; 1976.

An anomalous zymogram of LDH in the serum from a patient with liver cirrhosis is reported. Agar gel electrophoresis of serum showed an extra LDH band close to the anodic side of LDH5 and a wide band of LDH5. Gel filtration of the patient's serum in Sephadex G-200 demonstrated an abnormal LDH fraction eluted between IgG and macroglobulin in addition to a normal LDH component. Chromatographically abnormal LDH was demonstrated on agar gel as extra and wide LDH5 bands and resembled closely human hepatic LDH in its inhibition by urea or substrate, its stability against heat, and its K_m. Immunological analyses demonstrated that abnormal LDH could be in the state combined with IgG. The molecular weight of the complex estimated by gel filtration was approximately 300,000. Mixtures of the patient's heated serum with either normal or patient's hepatic LDH showed an abnormal LDH fraction by gel filtration, whereas the abnormal fraction was not demonstrated when heated normal serum was mixed with either normal or the patient's hepatic LDH. These results strongly suggest that the occurrence of an anomalous LDH zymogram in the patient's serum is due to a formation of LDH-IgG complex, which is based on the binding of essentially normal hepatic LDH and abnormal IgG.

2435 POTASSIUM AND MAGNESIUM DEPLETION IN PATIENTS WITH CIRRHOSIS ON MAINTENANCE DIURETIC REGIMES. (Eng.) Wheeler, P. G.; Smith, T.; Golindano, C.; Alam, A. N.; Wilkinson, S. P.; Edmonds, C. J.; *et al.* (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, England). *Gut* 18(9):683-687; 1977.

Total body potassium (^{40}K) and WBC potassium measurements were carried out in 19 patients with stable but decompensated cirrhosis maintained on diuretics for previous ascites. WBC magnesium was measured simultaneously with WBC potassium to determine whether magnesium depletion occurs in association with potassium depletion. Of 13 patients receiving spironolactone alone, none had a total body potassium below the expected lower limit of normal (3.5-5.0 mmol/l). Of six patients who were receiving frusemide (40 or 200 mg/day) together with spironolactone, two had low values. The results for WBC potassium were in agreement, and simultaneous measurements of WBC magnesium showed a close correlation, those with intracellular potassium depletion also having magnesium depletion. One such patient was treated with magnesium supplements (30 mmol/day, 1 month) without effect on the potassium level, although intracellular magnesium was improved. It is concluded that spironolactone alone is the treatment of choice in the maintenance management of such patients, that additional potassium would be unnecessary, and that additional frusemide should be avoided if possible.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

2468 GREY-SCALE ULTRASONOGRAPHY OF PORTAL VEIN. (Eng.) Webb, L. J.; Berger, L. A.; Sherlock, S. (Royal Free Hosp., Pond St., Hampstead, London NW3 2QG, England). *Lancet* 2(8040):675-677; 1977.

The results of gray-scale ultrasonography of the portal vein were compared with those of splenic venography or superior mesenteric arteriography. The state of the extrahepatic portal venous system was correctly assessed by grey-scale ultrasonography in 21 patients with extrahepatic portal vein obstruction tested, and the results agreed with those obtained by portal venography. In all 22 age-matched controls, a patent portal vein was displayed. The diameter of the portal vein on the ultrasound scan was significantly less in the 22 controls than in 18 patients with chronic liver disease. Grey-scale ultrasonography is a reliable, inexpensive, and noninvasive method for diagnosing extrahepatic portal vein obstruction.

2469 HISTOPATHOLOGICAL STUDIES ON THE PROGNOSIS OF BILIARY ATRESIA. (Eng.) Chiba, T. (Tohoku Univ. Sch. Medicine, Sendai 980, Japan). *Tohoku J. Exp. Med.* 122(3):249-258; 1977.

Liver specimens from 68 patients with biliary atresia were examined to correlate histology with the postoperative prognosis. The histological findings were classified by the degree of fibrosis, bile duct proliferation, bile plugs, giant cell transformation, and intralobular cholestasis. Morphometrical studies of the interstitial area, bile duct (ductules), intrahepatic portal vein, and intrahepatic artery were carried out and correlated with the age of the patients and with operative results. Marked fibrosis (cirrhosis) and interstitial areas occupying more than 35% of the sectional area of the liver specimen were indicative of a poor prognosis. Other factors that indicated poor postoperative bile excretion included (a) severe ductular proliferation, shown by proliferated bile ducts occupying more than 20% of interstitial areas, (b) no or slight intralobular cholestasis, and (c) marked interlobular cholestasis.

2470 CONTROLLED STUDY OF CHENODEOXYCHOLIC ACID AS A CHOLERETIC AGENT. (Eng.) Salvioli, G. F.; Zambarda, E.; Frigerio, G. (Inst. Internal Medicine, Univ. Modena, Modena, Italy). *Curr. Ther. Res.* 22(3):529-535; 1977.

A controlled double-blind trial was carried out in 12 patients after cholecystectomy to study the choleretic activity of chenodeoxycholic acid (CDCA) and of its combination with fentonium bromide. The patients received either placebo (control), 250 mg dehydrocholic acid (DHCA, as a reference drug), 250 mg chenodeoxycholic acid (CDCA), or 125 mg CDCA plus 20 mg fentonium bromide, all in capsule form. Each preparation was administered in a total dose of four capsules, one at 8 a.m., one at 11 a.m., one at 2 p.m., and one at 5 p.m. On the test day, the bile was collected from biliary fistula (T-tube) for periods of 24 hr starting from 8 a.m., on the assumption that after 4 to 5 days the external flow has a good correlation with the total flow.

The observations were carried out according to a balanced incomplete blocks design, comparing two preparations in each patient. The statistical analysis was performed using the intra-block information to adjust the means and the deviances of the experimental data. The drugs showed significant ($p<0.01$ or $p<0.05$) choleretic effects compared to placebo, whereas small and not significant differences between drugs were ascertained. The combination of CDCA and fentonium bromide, although containing a half dose of CDCA, produced a similar effect to the other active preparations. No side-effects occurred.

2471 RADIOLOGIC EVALUATION OF THE BILE DUCTS CONDITION AFTER SURGERY FOR CHOLELITHIASIS.

(Pol.) Zalewski, J.; Szmurlo, J.; Bernacki, E.; Markiewicz, W. (Clinic Gastroenterological Surgery, Inst. Surgery, Bialystok, Poland). *Pol. Tyg. Lek.* 32(10):385-388; 1977.

Postoperative cholangiography provides valuable information on anatomy of the bile ducts, condition and function of papilla, and is a test for correctly performed surgery. The test was performed on 534 patients fasted with Kehr's T-drains in the common bile duct on the 10-12th postoperative day. In each subject, three to four cholangiograms were made, and the last one was focused on the papilla. Correct shape, width, and arrangement of the bile ducts and passage of the radio-opaque substance into the duodenum were observed in four of eight patients. In 20% of the patients with plastics of the papilla, intrahepatic bile ducts were not visualized, and the passage of the contrast substance into duodenum was unhampered. In 22 patients, concretions overlooked during surgery were detected. Dilatation of the bile ducts was observed in 43 subjects with inflammatory contraction of the papilla. This diagnosis was of great practical significance, and prolonged external drainage was employed. Complete obstruction of the terminal part of common bile duct was found in 15 patients after surgery for carcinoma of the head of pancreas or duodenal papilla. Deposition of the contrast substance in the terminal part of Wirsung's duct was detected in 194 subjects, although its cause was not known. Properly performed cholangiography is safe and painless. It is an important test of prognostic significance.

2472 PITFALLS IN SERUM BILE ACID ANALYSIS IN PATIENTS WITH CHOLESTASIS: DIFFERING BIOCHEMICAL PROPERTIES OF 3-HYDROXYSTERIOD DEHYDROGENASES FROM WILD-TYPE AND MUTANT Ps. testosteroni.

(Eng.) Bolt, M. G.; Boyer, J. L. *In: Bile Acid Metabolism in Health and Disease.* Edited by G. Paumgartner and A. Stiehl. (Baltimore: University Park Press): 285-292; 1977.

The use of mutant *P. testosteroni* for the photofluorometric measurement of serum bile acids from patients with cholestasis resulted in values that were 30 to 50% lower than those obtained with wild-type *P. testosteroni.* The reason for this discrepancy was studied. Differences in substrate specificity for the unesterified 3β-OH group in the assay of cholestatic sera did not contribute to the difference. Rather, the discrepancy was due to a low affinity of the mutant enzyme for bile acid substrates and NADH degradation catalyzed by both the mutant and wild-type enzymes. The low affinity of the mutant enzyme can be abolished in assay systems that are of high ionic strength; there will be a concomitant slight decline in maximum velocity. The enzyme-associated degradation of NADH can be prevented by the use of hydrazine, either as the hydrate or the sulfate, or by further purification of the enzyme on Sephadex G-200. The data indicate that differences in biochemical properties between mutant and wild-type *P. testosteroni* must be considered if they are to be used with validity in the assay of bile acids. Optimal assay conditions using the two sources of enzyme may not always be interchangeable.

2473 INTERMITTENT CHOLESTATIC JAUNDICE AND NONMETASTATIC PROSTATIC CARCINOMA.

(Eng.) Reddy, A. N.; Grosberg, S. J.; Wapnick, S. (Brooklyn Veterans Admin. Hosp., 527/111, Brooklyn, NY 11209). *Arch. Intern. Med.* 137(11):1616-1617; 1977.

A patient with intermittent cholestatic jaundice and metastatic prostatic adenocarcinoma that had spared the liver and extrahepatic biliary tree is described. He had puzzling episodes of jaundice for 2.5 yr following a transurethral resection for the carcinoma. The results of appropriate investigations and an exploratory laparotomy performed during the patient's four antemortem hospitalizations were indicative of "recurrent intrahepatic cholestasis," the cause of which remained an enigma even after exploratory laparotomy. At autopsy, no evidence of hepatic metastases or extrahepatic biliary obstruction was found. Alcohol, hepatotoxic drugs, toxins, viral and chronic active hepatitis, hemolysis, and extrahepatic biliary obstruction were eliminated as causes of the jaundice. Intermittent intrahepatic cholestasis may be one of the nonmetastatic manifestations (nonmetastatic hepatopathy of malignancy) of prostatic adenocarcinoma.

2474 CLINICOPATHOLOGIC CLASSIFICATION OF CONGENITAL CYSTIC DILATATION OF THE COMMON BILE DUCT.

(Eng.) Matsumoto, Y.; Uchida, K.; Nakase, A.; Honjo, I. (Kyoto Univ. Medical Sch., Sakyo-Ku, Kyoto, Japan). *Am. J. Surg.* 134(5):569-574; 1977.

Congenital cystic dilatation of the common bile duct was classified in 103 patients with a localized dilatation of the biliary passages who were treated at the Kyoto University Medical Center between 1970 and 1975. Of the 103, 101 had congenital cystic dilatation of the common bile duct (Alonso-Lej type I). These dilatations were classified into two subtypes, "infant type" and "adult type," based on the anatomic location and clinical features. The infant type cyst was typically a large cyst of the choledochus and most common in infancy and childhood. The adult type cyst was a fusiform dilatation of the biliary tract, and most common in adults. Among the patients with the infant type cyst, six had a dilatation beginning in the intrapancreatic or retroduodenal portion of the common bile duct and ending below the level of the junction with the cystic duct, and seven had a dilatation rising as far as the common hepatic duct. Gallstones were present in four patients in the first category, and in one in the second category. Among the patients with the adult type cyst, 27 had dilatation involving the right and left hepatic ducts, and in 61 it involved the intrahepatic bile ducts together with the entire extrahepatic biliary system. Twenty-three patients in the first group had gallstones, and 47 in the second group had stones.

2475 THIN NEEDLE CHOLANGIOGRAPHY: EXPERIENCE WITH 50 PATIENTS. (Eng.) Goldstein, L. I.; Kadell, B. M.; Weiner, M. (Univ. California Los Angeles Center Health Sciences, Los Angeles, CA 90024). *Ann. Surg.* 186(5):602-606; 1977.

The diagnostic accuracy and safety of thin needle cholangiography (TNC) was assessed in 50 patients with obstructive jaundice or jaundice of obscure origin. TNC was performed using the Chiba needle. Obstructed ducts were successfully demonstrated in 100% of cases (29/29). Nonobstructed ducts were opacified in 12/21. Overall success was 82% (41/50). Two septic complications, which were documented by positive blood cultures for *Escherichia coli*, occurred. It is concluded that TNC is a highly reliable, easy, and safe procedure in the evaluation of the jaundiced patient. Accurate demonstration of the biliary anatomy by TNC provided important information that in 20% of all cases led to a change in diagnosis, avoidance of unnecessary procedures, and shortening of hospitalization. Failure to visualize nondilated biliary ducts occurred with advanced chronic liver disease or fatty liver.

2476 SURGICAL JAUNDICE IN INFANCY. (Eng.) Lilly, J. R. (Univ. Colorado Sch. Medicine, 4200 E. Ninth Ave., Denver, CO 80262). *Ann. Surg.* 186(5):549-558; 1977.

Surgical progress in the treatment of congenital malformations of the biliary system is reviewed. Kasai's hepatic portoenterostomy operation for biliary atresia is a most dramatic example of the revolutionary changes that this type of surgery has undergone in the last decade. Radical departures from conventional surgical treatment also have been advocated for choledochal cyst, Caroli's disease, congenital perforation of the bile ducts, and biliary hypoplasia. The lesions responsible for obstructive jaundice in the early months of life include biliary atresia, biliary hypoplasia, choledochal cyst, congenital dilatation of the intrahepatic bile ducts (Caroli's disease), inspissated bile plug, and congenital common bile duct perforation. In "correctable" biliary atresia (i.e., where the proximal bile ducts are patent but end blindly before the duodenum), the Roux-en-Y choledochojejunostomy is advocated, while the Kasai procedure is used in situations where the lumina of the ducts are obliterated. In biliary hypoplasia, hepatic portoenterostomy is recommended. Roux-en-Y choledochojejunostomy may be used in choledochal cyst and Caroli's disease. Simple peritoneal drainage and cholecystostomy are advocated in congenital common bile duct perforation.

2477 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY OR ULTRASONOGRAPHY FOR CHOLEDOCHOLITHIASIS [Abstract]? (Eng.) Zimmon, D. S.; Kedsiora, J.; Clemett, A. R. (St. Vincent's Hosp., Medical Center, New York, NY). *Gastroenterology* 73(5):1257; 1977.

GENERAL

2541 **GASTROINTESTINAL COMPLICATIONS AFTER RENAL TRANSPLANTATION.** (Eng.) Rosekrans, P. (Ikazia Hosp., Rotterdam, Netherlands). *Radiol. Clin. (Basel)* 47(1):32-43; 1978.

A total of 32 gastrointestinal complications were observed in 22 of 110 patients after renal transplantation. Gastrointestinal hemorrhage occurred in 12 patients, duodenal perforation in 1, *Candida* esophagitis in 6, severe hepatitis and liver failure in 8, pancreatitis in 2, abdominal fistulae and abscesses in 2, and ileus in 1. There were 9 fatalities as a result of these complications, and 7 of the deaths occurred among the 12 patients with severe gastrointestinal hemorrhage, as expressed by hematemesis and/or melena or bloody stools. Signs of liver failure were found in four patients with gastrointestinal hemorrhage; in three of these patients, this developed a few months after treatment of the bleeding, always after the development of Australia antigen-positive hepatitis. All three of these patients died, two in hepatic coma. The hepatitis B in these patients may have been the result of multiple blood transfusions received during the period of bleeding. Among the eight patients with severe hepatitis, four died in hepatic coma. Overall, upper gastrointestinal bleeding, particularly in combination with liver failure, was the principal cause of death in these patients. Two patients in this series were found to have malignancies, an adenocarcinoma of the stomach and a reticulum cell sarcoma localized in the brain and in the patient's own right kidney. These complications occurred 4 yr and 8 months, resp., after transplantation. The risk of solid tumor growth unmistakably increases as the time after transplantation increases.

2542 **EFFECTS OF ABDOMINAL SURGERY ON THE DEVELOPMENT OF RADIATION ENTEROPATHY.** (Eng.) LoIudice, T.; Baxter, D.; Balint, J. (Albany Medical Center Hosp., Albany, NY 12208). *Gastroenterology* 73(5):1093-1097; 1977.

A controlled, retrospective study of 105 patients was undertaken to ascertain whether or not abdominal surgery at any time before radiation therapy might result in an increased incidence of radiation enteropathy. Three groups of patients were studied; 24 had radiation enteropathy that developed an average of 12.5 months after radiation therapy, and 28 were matched controls without this complication. The records of a further group of 53 unmatched controls, who survived more than 2 yr after irradiation were also examined. In the group with radiation enteropathy, 18 (75%) had a history of prior surgery, whereas only 3 (10.7%) of the matched controls had been operated before irradiation ($\chi^2=3.52$, $p<0.005$). The incidence of prior surgery in the unmatched control group was 13.2%. These data indicate that abdominal surgery before radiotherapy does increase the risk of subsequent development of radiation enteropathy.

2543 **FECAL LEUKOCYTES IN ENTERIC INFECTIONS.** (Eng.) Pickering, L. K.; DuPont, H. L.; Olarte, J.; Conklin, R.; Ericsson, C. (6400 W. Cullen St., Houston, TX 77030). *Am. J. Clin. Pathol.* 68(5):562-565; 1977.

The value of the examination of stools for WBC as a diagnostic tool in enteric infections was examined. The feces of 90 adult and 200 pediatric patients were examined for the presence of fecal WBC and enteric pathogens during episodes of acute diarrhea. Fecal WBC were demonstrated in specimens from 24 of 35 patients with diarrheal stools from which a *Shigella* strain was isolated, and in 4 of 11 specimens from patients with stools from which *Salmonella* was isolated. A significantly ($p<0.001$) greater number of patients with *Shigella* isolated from their stools had fecal WBC when compared with 27 of 158 patients from whose stools no pathogen was isolated or to 8 of 56 patients from whose stools other bacterial and protozoal pathogens were isolated ($p<0.05$). An invasive bacterial strain was isolated from the stools of 18 patients, as determined by guinea pig eye testing. Eleven of 13 invasive *Shigella* isolates were associated with numerous fecal WBC, while none of five other invasive bacteria were related to WBC-positive stools. WBC were rarely found in the stools of patients with diarrhea thought to be due to viruses (2/36), *Giardia lamblia* (0/6), *Entamoeba histolytica* (0/4), or toxigenic *Escherichia coli* (4/35). The lack of total correlation between the presence of WBC and recovery of an invasive pathogen reflects the complex interaction of enteric pathogens with their hosts.

2544 USE OF AN ELEMENTAL DIET (VIVONEX) IN THE MANAGEMENT OF BILE ACID-INDUCED DIARRHOEA.

(Eng.) Nelson, L. M.; Carmichael, H. A.; Russell, R. I.; Atherton, S. T. (Royal Infirmary, Glasgow G4 OSF, Scotland). *Gut* 18(10): 792-794; 1977.

The effect of a low-fat containing elemental diet (Vivonex) on fecal bile acid excretion was studied in six patients with cholerheic diarrhea, two normal controls, and four patients with noncholerheic diarrhea. The total fecal bile acid excretion in the patients with bile acid-induced diarrhea was significantly reduced from 6.37 ± 1.64 mmol/24 hr to 2.70 ± 1.12 mmol/24 hr during Vivonex treatment ($p<0.05$). A marked improvement in the diarrhea of these patients occurred; the number of stools per day decreased, and there was less urgency associated with the diarrhea. No significant reduction in fecal bile acid excretion was observed for the control and noncholerheic diarrhea groups. A low-fat elemental diet may be valuable in the management of patients with bile acid-induced diarrhea unresponsive to other forms of therapy, and may be of particular value in patients with Crohn's disease.

2545 EXPERIMENTAL DIARRHOEA IN HUMAN VOLUNTEERS FOLLOWING ORAL ADMINISTRATION OF Clostridium perfringens ENTEROTOXIN.

(Eng.) Skjelkvale, R.; Uemura, T. (Norwegian Food Res. Inst., P.O. Box 50 N-1432 As-NLH, Norway). *J. Appl. Bacteriol.* 43(2): 281-286; 1977.

Experimental diarrhea was produced in human volunteers by the administration of *Clostridium perfringens* enterotoxin in an effort to study the following questions: (a) the amount of enterotoxin needed to produce diarrhea, (b) the enterotoxin level in fecal samples after acute diarrhea, (c) changes in serum anti-enterotoxin titers after experimental diarrhea, and (d) the role of anti-enterotoxin in the prevention of diarrhea in enterotoxin-exposed subjects. The p.o. administration of purified enterotoxin to the volunteers provoked diarrhea and abdominal pain. Diarrhea occurred in one of two volunteers who received 8 mg of enterotoxin. All of five subjects given 10 and 12 mg of purified enterotoxin or crude enterotoxin developed symptoms. Passive hemagglutination anti-enterotoxin titers in serum increased in only five of nine volunteers after exposure to enterotoxin. As such levels of anti-enterotoxin can be detected in normal serum samples, titration of anti-enterotoxin may be of little use in diagnosing *C. perfringens* food poisoning. Enterotoxin was detected in all diarrheal fecal specimens, and the enterotoxin level varied from 0.2-16 μg/g. The detection of enterotoxin in diarrheal feces may be the most reliable diagnostic procedure in outbreaks of *C. perfringens* food poisoning.

2546 DOGMA AND DERMATITIS HERPETIFORMIS. (Eng.)

Marks, J. M. (Royal Victoria Infirmary, Queen Victoria Rd., Newcastle upon Tyne NEI 4LP, England). *Clin. Exp. Dermatol.* 2(9):189-207; 1977.

Data from 120 patients with dermatitis herpetiformis (DH) seen in a 10-yr period were reviewed with reference to new discoveries in the field to demonstrate how the concept of DH has altered during the last decade. In these patients, the final diagnosis of DH was made from an overall impression, which took into account clinical symptoms, therapeutic response, histological examination, and the results of special tests. Dapsone response was essential for differentiation of DH from diseases not of the DH/pemphigoid group. The IgA test was performed on clinically uninvolved skin; IgA deposits were found in 53 of 55 patients. This test is a good screening procedure, but it should be used in conjunction with other diagnostic criteria. Some anomalies of the IgA test occurred, but their significance was uncertain. It is not known whether the enteropathy found in some patients with DH was celiac disease (CD). To answer this question more precise definition of CD is necessary.

2547 VITAMIN B_{12} ABSORPTION DETERMINED WITH A DOUBLE ISOTOPE TECHNIQUE EMPLOYING INCOMPLETE STOOL COLLECTION: RELIABILITY AND VALIDITY IN PERNICIOUS ANEMIA.

(Eng.) Hjelt, K.; Munck, O.; Hippe, E.; Barenholdt, O. (Glostrup Hosp., Glostrup, Denmark). *Acta Med. Scand.* 202(5):419-422; 1977.

To evaluate the reliability of the vitamin B_{12} absorption test, the vitamin B_{12} (B_{12}) absorption was determined simultaneously with whole-body counting (FRB_{12}) and with a double isotope technique employing incomplete stool collection (FAB_{12}) in 19 control patients and 10 patients with pernicious anemia (PA). The test dose was administered p.o. and consisted of 8 ml of a 10 ml solution containing 0.5 μg of $^{58}Co\text{-}B_{12}$ (0.4 μCi) and 2 mg of $^{51}CrCl_3$ (20 μCi). Two milliliters of the solution were used as the standard. To permit following of the passage of the inabsorbable tracer ($^{51}CrCl_3$), 25 radiopaque pellets and 4 carmine tablets (2 g) were administered to the patients immediately after the test dose. Counting of a 3-4 ml specimen from one of the first two red stools was sufficient for calculation of FAB_{12}. The findings correlated closely with the FRB_{12} values ($r=0.99$, $N=39$, $p<0.001$). In the control subjects, the FAB_{12} averaged 74% (range 37-88). In the patients with PA given intrinsic factor (IF), the FAB_{12} averaged 40% (range 22-59). When IF was not given, FAB_{12} averaged 2% (range 0-9). The test, therefore, is a valid indicator of pernicious anemia. For the mean value of 74%, the standard deviation (S.D.) was 5%, corresponding to a coefficient of variation (CV) of 7%. In the patients not given IF, S.D. was 1% and CV 50%, and in those given IF, S.D. was 8% and CV 20%. These results demonstrate that the test is as reliable as whole-body counting. Carmine tablets proved to be a good indicator of isotope-containing stool. The test is easy to perform and requires only a scintillation well-counter. No cooperation on the part of the patients is necessary. The test is also suitable for outpatients. Furthermore, it is independent of kidney function, and flushing with B_{12} is avoided.

2548 UNUSUAL AMYLOID BODIES IN HUMAN LIVER: ULTRASTRUCTURAL AND FREEZE-ETCHING STUDIES. (Eng.) Livni, N.; Behar, A. J.; Lafair, J. S. (Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel). *Isr. J. Med. Sci.* 13(12):1163-1170; 1977.

An unusual presentation of amyloidosis in the liver is described in two patients with chronic, nonspecific pulmonary disease. Amyloid bodies, ranging from 3 to 20 μm in diameter and staining positive for Congo red, were found to be deposited between or within hepatocytes and, therefore, to be in a more direct spatial relationship to epithelial than to Kupffer or sinusoidal lining cells. The freeze-etching technique revealed that the average diameter of the amyloid fibrils was 15 nm and not 7 to 10 nm; this may have been due to the fact that this technique avoids shrinkage artifacts that follow fixation and dehydration. These observations suggest a possible role of parenchymal tissues in the formation of amyloid material.

2549 IMPROVED MICELLAR DISPERSAL OF DIETARY LIPID BY BILE ACIDS DURING REPLACEMENT THERAPY IN GROWTH HORMONE-DEFICIENT CHILDREN. (Eng.) Poley, J. R.; Smith, J. D.; Thompson, J. B.; Seely, J. R. (Kinderklinik der Universitat Ulm, Prittwitzstrasse 43, 7900 Ulm, Donau, W. Germany). *Pediatr. Res.* 11(12):1186-1191; 1977.

To determine whether human growth hormone (hGH) influences digestive processes in man, the composition of the aqueous (micellar) phase was studied during the digestion of two consecutive meals in five growth hormone-deficient individuals and in three controls, before and after replacement therapy with hGH. Before treatment, the average micellar bile acid concentration in the hGH-deficient individuals was 5.0 ± 0.6 mM (normal controls 6-15 mM) during the first meal, and 3.5 ± 0.9 mM (normal controls 5-10 mM) during the second meal. After 1 yr of treatment with hGH (2 U 3x/week for 10 days, thereafter 3 U/week), the mean micellar bile acid concentration increased to 9.7 ± 1.0 mM ($p<0.02$) during the first, and to 7.1 ± 0.3 mM ($p<0.01$) during the second meal. The micellar lipid concentration increased concomitantly with an increased micellar bile acid concentration (fatty acid: first meal 6.3 ± 0.6 mM to 13.0 ± 0.7 mM, $p<0.001$; second meal 4.5 ± 1.5 mM to 8.5 ± 0.3 mM, $p<0.05$; monoglyceride, as percentage of total fatty acids: first meal 25 ± 10 to 53 ± 7, $p<0.02$; second meal 31 ± 7 to 62 ± 6, $p<0.02$). Short-term treatment (10 days) of the controls did not affect the concentration of micellar bile acids and lipids. There was no significant difference in the physical state of bile acids and lipids between patients and control subjects before and after treatment.

2550 SERUM ALBUMIN LEVELS IN PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Lamers, C. B. H.; Hafkenscheid, J. C. M.; Yap, S. H.; van Tongeren, J. H. M. (Univ. Hosp. St. Radboud, Nijmegen, Netherlands). *Gastroenterology* 73(5):975-979; 1977.

The serum albumin concentrations in patients with the Zollinger-Ellison (ZE) syndrome were compared with the levels in normal controls and in patients with duodenal or stomal ulcers. Serum albumin concentrations in 20 patients with proved or presumed ZE syndrome (4.1 ± 0.8 g/100 ml) were significantly ($p<0.01$) lower than the levels observed in 40 normal controls (5.1 ± 0.3 g/100 ml), 40 duodenal ulcer patients (5.1 ± 0.4 g/100 ml), and 20 stomal ulcer patients (5.1 ± 0.3 g/100 ml). Six ZE patients with metastatic gastrinoma had slightly lower ($p<0.10$) serum albumin concentrations (3.5 ± 0.9 g/100 ml) than did 14 ZE patients without evidence of metastatic lesions (4.3 ± 0.7 g/100 ml). In a small group of patients studied more extensively, the mechanism of hypoalbuminemia was found to be complex. In addition to metastatic tumor growth, both gastrointestinal protein loss and impaired albumin synthesis may be factors in the pathogenesis of hypoalbuminemia. Inadequate nutrition was only evident in one patient with esophageal stricture and in two patients with extensive tumor growth after total gastrectomy. Total gastrectomy induced a rise in serum albumin in all eight patients studied ($p=0.01$). It is concluded that low serum albumin concentrations in peptic ulcer patients may be a clue to the diagnosis of ZE syndrome.

2551 POSSIBILITIES OF THE SURGICAL MANAGEMENT OF HEMORRHAGES OF THE UPPER GASTROINTESTINAL TRACT. (Fle.) Eyskens, E. (St. Vincentius Ziekenhuis, Universitaire Instelling Antwerpen, Universiteitsplein 1, B-2610 Wilrijk, Belgium). *Tijdschr. Gastroenterol.* 19(5):347-359; 1976.

GENERAL

Parasitology

2615 HEPATIC AMEBIASIS, ANALYSIS OF 56 CASES. I. CLINICAL FINDINGS. (Eng.) Carneiro Chaves, F. J. Z.; Cruz, I.; Gomes, C.; Domingues, W.; Marques Da Silva, E.; Tavarela Veloso, F. (Hosp. de S. Joao, Porto, Portugal). *Am. J. Gastroenterol.* 68(2):134-140; 1977.

Clinical findings in 56 patients with hepatic amebiasis are reviewed. The clinical picture was dominated by abdominal pain (96.4%) localized in the right hypochondrium in 90.7% of the cases, fever (71.4%), anorexia (53.5%), weight loss (50%), tender hepatomegaly (85.7%), pain on percussion of the right hypochondrium (81.5%), and auscultatory abnormalities in the lower right lung field (71.4%). Mucosal edema (28.9%) and a granulated mucosa (28.9%) were the most frequent rectosigmoidoscopic findings in the 38 patients examined. Liver puncture biopsy and aspiration of abscesses were performed in 16 patients, and characteristic pus resembling anchovy sauce was obtained in 87.5% of these patients. Mild jaundice was observed in 35.7% of the patients and appeared to have no prognostic significance. The illness was most frequent in black men between the ages of 20 and 39 yr; 89.3% of the patients were men, 75% were black, and 70.9% were between 20 and 39 yr of age. Metronidazol (250 mg, p.o., for 10 days) was used to treat 15 patients; dehydroemetine (1 mg/kg, i.m., for 10 days) and tetracycline (1-2 g, p.o., for 14 days) were used to treat 31 patients; and chloroquine (750 mg/day, p.o., for 4-6 weeks) was given to 10 patients. Surgical intervention was necessary only when complications were present; however, even in a patient with a bronchohepatic fistula, complete recovery followed chemotherapy. Other, rarer complications, such as rupture into adjacent abdominal viscus, the pericardium, or the skin, were not observed.

2616 MASSIVE INFECTION WITH Fasciola hepatica IN MAN. (Eng.) Jones, E. A.; Kay, J. M.; Milligan, H. P.; Owens, D. (Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *Am. J. Med.* 63(5):836-842; 1977.

The 6-yr clinical course of a patient who acquired a massive *Fasciola hepatica* infection is described. A peripheral blood eosinophilia was an almost constant finding throughout the illness. The patient may have been infected with a multiple of 40 adult flukes, as his fecal ova count (1,000/g) was 40 times greater than that of a subject with an asymptomatic infection. During the illness, cholecystectomy was carried out. The surface of the liver was studded with greyish white hard nodules. Histologically, there was a nonspecific chronic cholecystitis; a liver biopsy disclosed florid changes of large duct, biliary obstruction, granulomas, patchy periductular fibrosis, and an ovum morphologically similar to an ovum of *F. hepatica* surrounded by a granuloma. Three exacerbations of symptoms were associated with severe microcytic hypochromic anemia, possibly due to blood loss into the biliary tract. A course of bithionol was associated with rapid amelioration of symptoms and disappearance of ova from feces. No evidence of recurrence occurred during the following 2.5 yr. The infection was probably acquired by eating wild watercress containing encysted metacercariae. At a campsite frequented by the patient, a habitat suitable for the life cycle of *F. hepatica* was found, including snails of the genus *Limnaea truncatula,* which were shown to contain cercariae. The site is in a region with a high rainfall, a factor known to favor the life cycle of *F. hepatica.* Infection with this parasite should be considered whenever a clinical picture suggestive of biliary tract disease is associated with an eosinophilia.

2617 QUANTIFICATION OF THE LYMPHOCYTIC INFILTRATE IN JEJUNAL EPITHELIUM IN GIARDIASIS. (Eng.) Wright, S. G.; Tomkins, A. M. (Hosp. Tropical Diseases, St. Pancras Way, London NW1, England). *Clin. Exp. Immunol.* 29(3):408-412; 1977.

To determine if there is an increased number of intraepithelial lymphocytes in the jejunum of patients with giardiasis, these cells were counted in coded serial sections of both normal jejunum and jejunum from 40 patients with giardiasis. Patients with giardiasis and normal intestinal absorption and control patients who had lived and traveled in tropical areas had similar counts, which were higher than those reported for controls from temperate areas. Where giardiasis was accompanied by malabsorption of one substance, the mean count was significantly higher than that of controls ($p<0.02$). In those patients with giardiasis and malabsorption of two or three substances, the mean count was significantly higher than that of controls ($p<0.02$) and that of patients with giardiasis and normal absorption ($p<0.05$). After treatment, intraepithelial lymphocyte counts declined consistently in patients with malabsorption. There appears to be an association between raised intraepithelial lymphocyte counts and malabsorption.

2618 A STRANGE CASE OF ASTHENIA DUE TO THERAPY ON THE BASIS OF ERRONEOUS DIAGNOSIS IN A PATIENT WITH SCHISTOSOMIASIS. (Fre.) Simitzis-Le-Flohic, A. M.; Chastel, Cl.; Le Roy, J. GENERAL

Regional Enteritis

2623 ^{14}C-GLYCOCHOLATE TEST IN CROHN'S DISEASE--ITS VALUE IN ASSESSMENT AND TREATMENT. (Eng.) Scarpello, J. H. B.; Sladen, G. E. (Royal Hosp., West St., Sheffield, England). *Gut* 18(9): 736-741; 1977.

The ^{14}C-glycocholic acid (^{14}C-GCA) test was assessed in 27 patients who had resection of the ileum and colon for Crohn's disease and in 19 patients with unoperated stable Crohn's disease. The incidence of increased breath output of $^{14}CO_2$ and fecal output of ^{14}C was significantly greater in operated patients. Six operated patients had increased breath output alone, 8 had increased fecal output alone, and 12 had increased fecal and breath output, whereas the respective figures in 13 nonoperated patients were 2, 7, and 0. Half the unoperated patients had normal results and, of the others, a modest increase in fecal ^{14}C was the usual finding. There was no correlation between the ^{14}C-GCA test, the Schilling test, and the extent and severity of the radiological signs in the unoperated patients. Metronidazole therapy was poorly tolerated and had little or no influence on symptoms but did decrease the excretion of $^{14}CO_2$ in the breath when the ^{14}C-GCA test was repeated. Cholestyramine therapy was beneficial in the majority of resected patients with diarrhea and an increased fecal ^{14}C excretion, and, on repeat testing, there was a significant increase in the output of breath $^{14}CO_2$. The beneficial effect was less marked in the unoperated patients, and the breath $^{14}CO_2$ output remained normal in those retested. Interruption of the enterohepatic circulation of bile acids did not seem to make an important contribution to the symptoms of patients with stable unoperated (and uncomplicated) Crohn's disease, even when the ileum was extensively involved.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

2629 ESTIMATION AND CHARACTERIZATION OF PROSTAGLANDINS IN THE HUMAN GASTROINTESTINAL TRACT. (Eng.) Bennett, A.; Stamford, I. F.; Stockley, H. L. (King's Coll. Medical Sch., Denmark Hill, London SE5 8RX, England). *Br. J. Pharmacol.* 61(4): 579-586; 1977.

To characterize the prostaglandin extracted from muscle and mucosa of various regions of the human gut, and to study prostaglandin synthetase extracted from colonic mucosa, prostaglandin-like material was extracted from muscle and mucosa of surgically removed human tissues and assayed against prostaglandin E_2 on strips of rat gastric fundus. Superfused human isolated gastric mucosa released prostaglandin-like material, and release was increased by stretching or clamping the tissue. The relative amounts of extracted biological activity were noted broadly as follows: gastric antral mucosa>colon muscle>gastric body mucosa≃ileal mucosa>colon mucosa≃gastric muscle≃ ileal muscle. Prostaglandins E and F were tentatively identified by chromatography and sensitivity to inactivation by alkali. Prostaglandin E apparently contributed most to the biological activity, possibly because the assay tissue is more sensitive to prostaglandin E than to F. Chromatography of gastric body mucosal extracts located material running with prostaglandin E_2 and a little with E_1. Colonic muscle and mucosal extracts contained material with relative front (R_F) values of prostaglandin E_1, E_2, E_3, and $F_{1\alpha}$, whereas $F_{2\alpha}$- and $F_{3\alpha}$-like substances were found only in the mucosa. The proportion of prostaglandin F varied from one specimen to another. The amount of extracted prostaglandin-like activity was increased by adding cofactors and arachidonic acid, and decreased by homogenization with acid-ethanol. The type and amount of activity generated from arachidonic acid by partly purified colonic mucosal prostaglandin synthetase depended on the substrate concentration.

2630 EFFECT OF CHRONIC ETHANOL INGESTION ON THE SMALL INTESTINAL ULTRASTRUCTURE IN RATS. (Eng.) Rossi, M. A.; Zucoloto, S. (Medical Sch. Ribeirao Preto, 14100, Ribeirao Preto, Sao Paulo, Brazil). *Beitr. Pathol.* 161(1):50-61; 1977.

The effect of chronic ethanol ingestion on small intestinal ultrastructure was studied in male Wistar rats. Rats maintained for 16 weeks on a supplemented solid semisynthetic diet plus ethanol, corresponding to 35% of the total caloric intake, developed ultrastructural changes in the small intestine as compared to pair-fed controls. The enterocytes from jejunal and ileal villi of the alcoholic animals exhibited conspicuous alterations of the mitochondria and both smooth and rough endoplasmic reticulum. The mitochondrial changes were characterized by enlargement, swelling, decreased matrical density, ruptured cristae, and occasional myelin figures. The smooth endoplasmic reticulum was dilated and apparently proliferated in a few epithelial cells. The rough endoplasmic reticulum appeared scarce, with fewer ribosomes attached to the cisternae. These findings provide further evidence that chronic ethanol consumption is important in the pathogenesis of small intestinal damage in rats. These changes could be responsible, at least in part, for the functional abnormalities commonly found in chronic alcoholism.

2631 INTESTINAL MUCOSAL CHANGES FOLLOWING INDUCED HYPOTHYROIDISM IN THE DEVELOPING RAT. (Eng.) Blanes, A.; Martinez, A.; Bujan, J.; Junquera, S. R. C.; Carballido, S. M. (Departamento de Anatomia Patologica del Hospital Clinico de S. Carlos, Universidad Complutense, Madrid, Spain). *Virchows Arch. [Pathol. Anat.]* 375(3):233-239; 1977.

Morphological changes in the small intestine were studied in neonatal, hypothyroid rats. Hypothyroidism was induced during the first 24 hr postnatally in Wistar rats by the injection of radioiodine (100 μCi, i.p.). Samples from duodenojejunal and ileocecal junctions were taken, and histologic, histomorphometric, and ultrastructural studies were carried out. The most prominent feature was the decrease of the villous height and total mucosal thickness in the hypothyroid animals in comparison with controls. At the electron microscopic level, the microvillous height was also markedly decreased. These changes probably represent a direct effect of hormonal deprivation upon the intestinal mucosa, combined with the effect that hypothyroidism may have on the villi.

2632 ULTRASTRUCTURAL EFFECTS OF PARACHLOROPHENYLALANINE, 5-HYDROXYTRYPTAMINE AND THE IMIPRAMINE GROUP ON THE NERVE PROCESSES OF THE SMALL INTESTINE. (Eng.) Feher, E.; Csanyi, K. (Semmelweis Univ. Medical Sch., Budapest, Hungary). *Acta Anat.* 100(1):61-67; 1978.

The structure of the nerve fibers in the isolated cat ileum was studied by fluorescence and electron microscopy after intraluminal treatment with imipramine group compounds, parachlorophenylalanine, and 5-hydroxytryptamine. Following treatment with parachlorophenylalanine (100 mg/kg/day, 5 days) and imipramine group compounds (30 mg/kg/day, 5 days), specific granules were selectively decreased ($p<0.001$) in number in the small intestinal nerve fibers. In concordance with ultrastructural observations, a marked diminution of fluorescence intensity was demonstrated in the small intestine. The number of the granular vesicles was significantly increased following 5-hydroxytryptamine treatment (500 mg/kg/day, as creatinine sulfate-H_2O complex, 5 days), and yellow fluorescent neurons and processes were observed in the myenteric and submucous plexuses. These observations demonstrate the serotoninergic nature of certain nerve fibers.

2633 CARCINOEMBRYONIC ANTIGEN (CEA) IN THE NORMAL HUMAN SMALL INTESTINE: A LIGHT AND ELECTRON MICROSCOPIC STUDY. (Eng.) Isaacson, P.; Judd, M. A. (General Hosp., Southampton, England). *Gut* 18(10):786-791; 1977.

To examine the localization of carcinoembryonic antigen (CEA) in the normal small intestine, an immunoperoxidase method was applied to formalin-fixed paraffin-embedded and glutaraldehyde-fixed resin-embedded sections of human small intestine. CEA was easily demonstrated coating the surface of the small intestine, lining the crypts, and in goblet cells, indicating its presence there in considerable concentration. At the ultrastructural level, CEA was localized in the glycocalyx and in mucin granules of goblet cells but not intracytoplasmically. The restriction of CEA staining to the goblet cells and the glycocalyx suggests that the glycocalyx, or part of it, may be derived from the goblet cell.

2634 DISTRIBUTION OF INTRINSIC FACTOR-VITAMIN B_{12} RECEPTORS IN HUMAN INTESTINE. (Eng.) Hagedorn, C. H.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Gastroenterology* 73(5):1019-1022; 1977.

A new rapid and accurate method for detecting vitamin B_{12}-intrinsic factor (IF-B_{12}) receptors is described, and this method was used to study the distribution of mucosal IF-B_{12} receptors in three human small intestines. A microfuge technique was used to detect the IF-B_{12} receptor; in this method, the sample was diluted after incubation, obviating washing, and multiple samples were processed at the same time. This technique was compared with the Millipore filter method, and a good correlation was observed; similar values for bound B_{12} were obtained, over a range of B_{12} concentrations, when the two techniques were used on identical samples. Using the new method, IF-B_{12} receptors in human intestine were found to be present in significant amounts in the entire distal three-fifths of intestine. Triokinase activity was absent in the distal two-fifths of intestine, and tryptophan oxygenase was present only in the distal one-sixth, or most terminal part of the ileum. These data suggest that (a) biochemical functions in the ileum have different anatomical distributions, (b) IF-B_{12} receptors correspond most closely with the accepted anatomical definitions of the ileum, and (c) vitamin B_{12} malabsorption seen in resection or disease of the terminal ileum may not be attributable solely to a deficiency of ileal receptors.

2635 AN ELECTRON MICROSCOPIC STUDY OF INTRA-EPITHELIAL LYMPHOCYTES IN HUMAN FETAL SMALL INTESTINE. (Eng.) Orlic, D.; Lev, R. (New York Medical Coll., Basic Science Bldg., Valhalla, NY 10595). *Lab. Invest.* 37(6):554-561; 1977.

To study intra-epithelial lymphocytes in the human fetal small intestine, small intestine was obtained from 8- to 20-week fetuses, and the tissues were examined by electron microscopy. Lymphocytes were present as isolated cells in the mucosal mesenchyme as early as the 8th week of intra-uterine life and were found, in increasing numbers, in the epithelium of specimens obtained from 11- to 20-week-old fetuses. All intra-epithelial lymphocytes were located in the lateral spaces between contiguous columnar cells. Some displayed cytoplasmic pseudopods and were thought to migrate within the extracellular spaces of the epithelial layer. Surface invaginations and cytoplasmic vesicles in fetal lymphocytes suggested that these cells were capable of pinocytotic activity. Intra-epithelial lymphocytes in fetal gut may be able to sample ingested foreign substances in swallowed amniotic fluid in a manner similar to that previously proposed for intra-epithelial lymphocytes in the ileum of young adult chickens.

2636 ULTRASTRUCTURAL IDENTIFICATION OF A NEW CELL TYPE--THE N-CELL AS THE SOURCE OF NEUROTENSIN IN THE GUT MUCOSA. (Eng.) Helmstaedter, V.; Feurle, G. E.; Forssmann, W. G. (Anatomisches Institut und Medizinische Poliklinik der Universitat Heidelberg, Heidelberg, W. Germany). *Cell Tissue Res.* 184(4):445-452; 1977.

Neurotensin cells were identified immunohistochemically and ultrastructurally by differential counting of endocrine cells in the small intestines of primates (*Tupaia belangeri*). Using light microscopy, the enterochromaffin (EC) cells were identified by the Masson-Fontana silver stain; with the same method the neurotensin cells were not stained. The other endocrine cells were quantified using the peroxidase-antiperoxidase stain with antisera against glucagon, somatostatin, cholecystokinin, gastrin, secretin, pancreatic polypeptide, gastric inhibitory peptide, and neurotensin. In the ileal mucosa, the most frequent endocrine cell was the EC cell, followed by the glucagonoid cell (L cell). The immunoreactive neurotensin cell was the third most frequent endocrine cell in this region. Ultrastructurally, this cell was found to contain electron dense secretory granules measuring 335 ± 87 nm in diameter.

2637 HISTOCHEMICAL AND ULTRASTRUCTURAL IDENTIFICATION OF NEUROTENSIN CELLS IN THE DOG ILEUM. (Eng.) Frigerio, B.; Ravazola, M.; Ito, S.; Buffa, R.; Capella, C.; Solcia, E.; Orci, L. (Histochemistry and Ultrastructure Center, Univ. Pavia at Varese, Viale L. Borri 57, I-21100 Varese, Italy). *Histochemistry* 54(2):123-131; 1977.

Neurotensin immunoreactive cells were investigated histochemically and ultrastructurally in the dog ileum, with special reference to their relation with other endocrine cells in the mucosa of the lower small intestine. Neurotensin cells that were stained with immunofluorescence or immunoperoxidase proved distinct from argentaffin (EC) cells, glucagon immunoreactive (GLI) cells, and pancreatic peptide immunoreactive (PP) cells. Neurotensin cells showed various degrees of reactivity with Grimelius silver. With electron microscopy, large granule cells with a thin peripheral rim of Grimelius-reactivity (L cells) and large granule cells with variable Grimelius-reactivity of the core (N cells) were found in addition to EC cells. On the basis of their distribution, L cells were identified with GLI cells, and N cells were interpreted to be neurotensin cells.

2638 ANATOMY AND RADIOLOGY OF THE AREAE GASTRICAE. (Eng.) Mackintosh, C. E.; Kreel, L. (Royal Free Hosp., Middlesex, England). *Gut* 18(11):855-864; 1977.

The anatomy and radiology of the areae gastricae were studied in human and pig stomach specimens to create a meaningful clinical picture of the anatomy of the gastric mucosa for the rational interpretation of the double-contrast barium meal. By coating isolated stomach sections with barium from a syringe, a barium groove pattern was observed that corresponded with the anatomical groove pattern in the human and pig. This pattern was distinctive in the anatomical antrum, body, and fundus of the stomach. The mosaic pattern in the antrum was relatively fine with a short distance between the grooves and, on occasion in the magnified image, there was an impression of a punctate pattern between the grooves themselves. In the anatomical body of the stomach containing the fundic glands, the grooves were much wider and further apart with a coarse mosaic quite different from the antral mucosa; a punctate pattern between the grooves was not clearly seen. The anatomical fundus had a groove pattern intermediate in coarseness between the antrum and body of the stomach. In 272 double-contrast barium meals in humans, the antral areae pattern was graded from 1-4, i.e., average distance between grooves 1, 2, 3, or 4 mm, with nonvisualization graded as 0. It was found that 35% of the duodenal ulcer cases had a grade 4 pattern in the antrum, and less than 3% of the duodenal ulcers occurred in the nonvisualized group. The inference is that the non-coater has a thick barrier mucus layer and a low duodenal ulcer incidence, that is in keeping with experimental work on rats showing that drugs that promote ulcer healing increase mucus secretion. It was also shown that the success of the barium coating to show the area gastricae depends on the type of barium used and the thickness of the barium coat itself in addition to the thickness of the mucus layer.

2639 MORPHOLOGICAL STUDY OF THE PANETH CELL: PANETH CELLS IN INTESTINAL METAPLASIA OF THE STOMACH AND DUODENUM OF MAN. (Eng.) Matsubara, F. (Yamaguchi Univ. Sch. Medicine, Kogushi, Ube, Yamaguchi Pref. 755, Japan). *Acta Pathol. Jpn.* 27(5):677-695; 1977.

To clarify the physiological significance of the Paneth cells, these cells were studied ultrastructurally in the duodenum and in intestinal metaplasia of stomach in 173 patients, and the fine structures of the cells were compared. Paneth cells showed the ultrastructure of serozymogenic cells and secreted their secretory granules by a merocrine process. Rod-shaped or tubular dense bodies were observed in the apical region of some Paneth cells, and these may have some relation to the secretion of the secretory granules. Secretory granules with a less dense layer in the periphery were also observed. Cells morphologically intermediate between the Paneth cell and the goblet cell were found. Some of the Paneth cells might be phagocytized by undifferentiated crypt cells. The Paneth cells in intestinal metaplasia were morphologically similar to those in duodenum. However, phagolysosomes in the lower cytoplasm were observed more frequently in the Paneth cells of the duodenum than in those found in gastric metaplasia.

2640 QUANTITATIVE ELECTRON MICROSCOPICAL STUDIES ON IN VITRO INCUBATED RABBIT GALLBLADDER EPITHELIUM. (Eng.) Blom, H.; Helander, H. F. (Dept. Anatomy, Univ. Umea, S-901 87 Umea, Sweden). *J. Membr. Biol.* 37(1):45-61; 1977.

Water and electrolyte transport were studied in pieces of rabbit gallbladder incubated *in vitro* for 1 hr in Ringer's solution at 37 C (transporting epithelium), or in Ringer's containing 1 mM ouabain (inhibited epithelium). The tissues were fixed in 2% glutaraldehyde, postfixed in OsO_4, and embedded in Epon. Stereological analysis was carried out on electron micrographs. In the transporting epithelium, the epithelial cell height averaged 28 μm in the crests and 18 μm in the crypts. The nucleus, mitochondria, paracellular channels, lateral plasma membrane, and apical membrane in the crests averaged 16.9% of cell volume, 18.7% of cytoplasmic volume, 28.3% of epithelial volume, 4.1 m^2/cm^3 of cell volume, and 0.5 m^2/cm^3 of cell volume, resp.; in the crypts, the corresponding figures were 18.7%, 14.1%, 11.0%, 2.9 m^2/cm^3, and 0.6 m^2/cm^3. The paracellular channels appeared as interconnected tissue sheets of varying width; they were broader in the basal portion of the epithelium than in the apical portion; however, immediately above the basement membrane the channels became very narrow. The arithmetic mean width of the channels was 0.9 and 0.2 μm in the crests and crypts, resp.; and their length was in the range of 40-120 μm. These stereological data are compatible with the standing gradient model for water transport. The ouabain-inhibited cells were swollen and had collapsed paracellular channels. Although it cannot be ruled out that volume changes occurred in the cells and the paracellular channels during the tissue processing, qualitatively similar morphology was observed by light microscopy of transporting and inhibited gallbladder epithelium fixed by freeze-drying and embedded in Epon. This indicates the presence of such channels in the *in vitro* transporting rabbit gallbladder epithelium.

ABSORPTION - EXCRETION - TRANSPORT

2649 ISOLATED MEMBRANE VESICLES AS TOOLS FOR ANALYSIS OF EPITHELIAL TRANSPORT. (Eng.) Hopfer, U. (Sch. Medicine, Case Western Reserve Univ., Cleveland, OH 44106). *Am. J. Physiol.* 233(6):E445-E449; 1977.

Vesicles of the isolated brush border and basolateral plasma membranes were used in studies of intestinal transport to provide information on mechanisms of solute translocation across both plasma membranes, coupling of Na$^+$ and nonelectrolyte transport in the brush border membrane, kinetics of the nonelectrolyte transport under controlled *cis* and *trans* conditions, and analysis of transport changes associated with different physiological or pathological conditions. The mechanisms of translocation of D-glucose and a neutral amino acid are presented as the examples of nonelectrolytic transport. It was found that Na$^+$ stimulated the transport of L-valine and D-glucose in brush border membranes. Further observations suggested that Na$^+$ is the only ion directly involved in nonelectrolyte transport. D-glucose translocations across the membrane fall into the category of "facilitated diffusion." The difference between the transport mechanisms in the brush border and the basolateral plasma membrane is the requirement for a cosubstrate in the former. The kinetic parameters of the Na$^+$-dependent glucose system, determined with an equilibrium exchange procedure, indicate that Na$^+$-glucose-loaded carrier has a significantly higher translocation rate than the carrier loaded only with D-glucose. Semistarvation of animals from which brush border membranes were isolated increased the activity of L-valine transport, which may explain the elevated amino acid transport seen in an intact epithelium. Semistarvation had no effect on the D-glucose transport rate. The experiments discussed illustrate that the advantage of the vesicular system preparations over preparations of intact intestinal cells or tissues is their ability to control the composition of the environment on both sides of the membrane and, thereby, the transmembrane gradients.

2650 EFFECT OF DAILY ETHANOL INGESTION ON INTESTINAL PERMEABILITY TO MACROMOLECULES. (Eng.) Worthington, B. S.; Meserole, L.; Syrotuck, J. A. (Nutrition Div., Univ. Washington, Child Development Mental Retardation Center, WJ-10, Seattle, WA 98195). *Am. J. Dig. Dis.* 23(1):23-32; 1978.

The effects of regular ethanol ingestion on morphological and permeability characteristics of the small intestine were assessed in mature female Sprague-Dawley rats. Thirty adult rats were divided into two groups and provided a standard commercial diet in pellet form. Each morning, after an overnight fast, every animal in the experimental group was administered an aliquot of 20% ethanol by gavage; animals in the control group were provided aliquots of 20% sucrose in water by the same method. After 4 and 8 weeks on the gavage routine (and 10 days and 4 weeks after gavage cessation), jejunal permeability to horseradish peroxidase was examined in animals from each group. Using a routine ligated-loop procedure and light and electron microscopy, ethanol-exposed rats demonstrated increased intestinal permeability to horseradish peroxidase by 4 weeks; sucrose-exposed animals revealed little alteration in mucosal integrity. It is proposed that regular ingestion of sizable amounts of alcohol alters morphological characteristics of the gut and increases the permeability of the mucosa to "undigested" macromolecules.

2651 EFFECTS OF ETHANOL ON SODIUM, 3-O-METHYL GLUCOSE, AND L-ALANINE TRANSPORT IN THE JEJUNUM. (Eng.) Kuo, Y. J.; Shanbour, L. L. (Univ. Texas Medical Sch. at Houston, Houston, TX 77030). *Am. J. Dig. Dis.* 23(1):51-56; 1978.

The effects of ethanol on Na^+, Cl^-, 3-*O*-methyl glucose (3-*O*-MG), and L-alanine fluxes were studied in the isolated rabbit jejunal mucosa. Ethanol (3% volume/volume present on both sides of the mucosa) decreased electrical potential difference (PD), short-circuit current (I_{SC}) and inhibited active transport of Na^+, 3-*O*-MG, and L-alanine. This concentration also increased the permeability of the mucosa for Cl^-, 3-*O*-MG, and L-alanine. Ethanol at 5.4% potentiated the effects on PD, I_{SC}, and the permeability for electrolytes and organic substances. These effects of ethanol could not be fully explained by an osmotic action. The results suggest that ethanol, by inhibiting intestinal absorption of Na^+, 3-*O*-MG, and L-alanine and enhancing possible fluid loss through increased permeability, may produce an effective nutritional deficiency even with adequate dietary intake.

2652 AMINO ACID TRANSPORT IN BRUSH-BORDER-MEMBRANE VESICLES ISOLATED FROM HUMAN SMALL INTESTINE. (Eng.) Lucke, H.; Haase, W.; Murer, H. (Max-Planck-Institut fur Biophysik, Kennedyallee 70, 6000 Frankfurt [Main], W. Germany). *Biochem. J.* 168(3):529-532; 1977.

L-alanine and L-phenylalanine uptake by purified brush border membrane vesicles isolated from human small intestine was investigated using a rapid-filtration technique. L-alanine entered the same osmotically reactive space as D-glucose, indicating that transport into the vesicles rather than binding to the membranes was occurring. The uptake rate for L-alanine was higher in the presence of a Na^+ gradient than in the presence of a K^+ gradient. In the presence of a Na^+ gradient, the lipophilic anion SCN^- caused an increase in L-alanine transport, whereas the nearly impermeant $SO_4{}^{2-}$ anion decreased the uptake of L-alanine compared with its uptake in the presence of Cl^-. The uptake of L-phenylalanine into the brush border membrane vesicles was also stimulated by Na^+. The results indicate that Na^+ and neutral amino acids are cotransported in the human intestinal brush border membrane.

2653 ASCORBIC ACID FLUX ACROSS MUCOSAL BORDER OF GUINEA PIG AND HUMAN ILEUM. (Eng.) Mellors, A. J.; Nahrwold, D. L.; Rose, R. C. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Am. J. Physiol.* 233(5): E374-E379; 1977.

The unidirectional influx of L-$[^{14}C]$ascorbic acid across the mucosal border of guinea pig and human ileum was determined. Influx was found to follow saturation kinetics, indicating that a carrier mechanism is operative. The maximal influx in guinea pig ileum bathed in Ringer solution was 140 nmol/cm^2/hr, and the ascorbic acid concentration required to give a half-maximal influx (K_m) was 1.0 mM. At mucosal ascorbic acid concentrations greater than 6 mM, or when the tissue was bathed in Na-free media, influx was approximately linearly related to the ascorbic acid concentration, and absorption by simple diffusion may predominate. With a mucosal ascorbic acid concentration of 0.28 mM, influx was reduced by at least 70% when Na-free media was used; however, influx was not dependent on the intracellular Na concentration. The brush border mechanism appears to be stereospecific and not closely coupled to cellular metabolism. A model of transport is favored that features a carrier-mediated transport mechanism for simultaneous entry of ascorbic acid and Na across the brush border. This model is similar in nature to, but functionally distinct from, the sodium-gradient mechanism postulated to effect sugar and amino acid transport in mammalian ileal mucosa.

2654 CHARACTERIZATION AND EFFECT OF PHOSPHOLIPID ON BILE ACID ABSORPTION BY VILLI ISOLATED FROM HAMSTER SMALL INTESTINE. (Eng.) Fondacaro, J. D.; Rodgers, J. B. (Univ. Cincinnati Coll. Medicine, 231 Bethesda Ave., Cincinnati, OH 45267). *Am. J. Dig. Dis.* 23(1):12-17; 1978.

The effects of phospholipid on absorption of bile acids by hamster small intestine were studied to determine if this compound inhibits absorption of bile acids. Taurocholic and cholic acid absorption was studied using a new *in vitro* technique that relates uptake rates to the weight of the villi present on the intestinal sample rather than to the weight of the entire segment of intestine used for the study. This procedure removes from consideration various components of the intestinal wall that are not directly involved with the absorptive process. Using radioactive techniques, absorption of each type of bile acid was determined over a broad range of concentrations both in the presence and absence of phospholipid in the incubation medium. Absorption of taurocholic acid by the jejunal villi was determined to be a passive process, as previously reported. Villi from the ileum absorbed both bile acids by an apparent active process when initial concentrations of bile acids were below 2.0 mM. Above this concentration, bile acid absorption by the ileum appeared to be mainly passive. Phospholipid inhibited bile acid absorption by the ileum when initial bile acid concentrations were moderately high. However, at low substrate concentration, phospholipid has no appreciable effect on bile acid transport.

2655 DISTRIBUTION AND CONTENT OF MICROTUBULES IN RELATION TO THE TRANSPORT OF LIPID. AN ULTRASTRUCTURAL QUANTITATIVE STUDY OF THE ABSORPTIVE CELL OF THE SMALL INTESTINE.

(Eng.) Reaven, E. P.; Reaven, G. M. (Stanford Univ. Sch. Medicine, Palo Alto, CA 94304). *J. Cell Biol.* 75(2, Part 1):559-572; 1977.

To determine whether microtubules are linked to intracellular transport in absorptive cells of the proximal intestine, microtubule distribution and content were determined in cells from fasting and fed female Sprague-Dawley rats. The animals received a meal of standard chow that was consumed during a 1-hr period, and tissue was taken from the mid-jejunum before, and 0.5 hr and 6 hr after the meal. The microtubule content of apical, Golgi, and basal regions of cells was quantitated by point-counting stereology. Microtubules were localized in intracellular regions of enterocytes (apical and Golgi areas) previously shown to be associated with lipid transport. The microtubule content within apical and Golgi regions was significantly ($p<0.01$) reduced during transport of foodstuffs. To determine the effect of inhibition of microtubule assembly on transport, colchicine or vinblastine sulfate was administered to postabsorptive rats, and the lipid and microtubule content of enterocytes determined 1 and 3 hr later. After treatment with these agents, lipid was found to accumulate in apical regions of the cells; this event was associated with a significant reduction in microtubule content. The regional distribution of microtubules in enterocytes, the decrease in assembled microtubules after a fat-containing meal, and the accumulation of lipid after the administration of antimicrotubule agents suggest that microtubules are related to lipid transport in enterocytes.

2656 EFFECTS OF DIHYDROXY BILE ACIDS AND HYDROXY FATTY ACIDS ON THE ABSORPTION OF OLEIC ACID IN THE HUMAN JEJUNUM.

(Eng.) Wanitschke, R.; Ammon, H. V. (I. Med. Klinik. d. Universitat, Langenbeck Str. 1, 6500 Mainz, W. Germany). *J. Clin. Invest.* 61(1):178-186; 1978.

Perfusion studies of the normal human jejunum were carried out in healthy men to determine whether dihydroxy bile acids and hydroxy fatty acids inhibit oleic acid absorption. Deoxycholate (3 mM) and glycodeoxycholate (7 mM) inhibited the absorption of 3 mM oleic acid in isotonic micellar solutions while inducing net fluid secretion. Similarly, fractional absorption of oleic acid decreased in the presence of hydroxy fatty acids. However, only the changes induced by 2 mM ricinoleic acid could be distinguished from changes induced by an increase in total fatty acid concentration. Under all experimental conditions, close linear relationships existed between net water movement and fractional absorption of glucose, xylose, and fatty acids, as well as between the absorption rates of these solutes. In contrast, net fluid secretion induced by hypertonic D-mannitol (450 mOsm/l) had no effect on solute absorption. The observations help explain the malabsorption of fat and other nutrients in patients with the blind loop syndrome.

2657 EFFECTS OF LONG CHAIN FATTY ACIDS ON SOLUTE ABSORPTION: PERFUSION STUDIES IN THE HUMAN JEJUNUM.

(Eng.) Ammon, H. V.; Thomas, P. J.; Phillips, S. F. (Veterans Admin. Center, Wood, WI 53193). *Gut* 18(10):805-813; 1977.

Perfusion studies were carried out in healthy volunteers to test the hypothesis that net fluid secretion induced by fatty acids is accompanied by parallel reduction in solute transport. Ricinoleic acid (≥ 2 mM) provoked a marked net secretion of fluid and concomitantly inhibited the absorption of all solutes tested (glucose, xylose, L-leucine, L-lysine, folic acid, and 2-mono-olein). Oleic acid (≤ 5 mM) also reduced net fluid and solute transport, but was less potent in reducing solute absorption than was ricinoleic acid. When fluid secretion was induced osmotically with mannitol, glucose and xylose absorption was not affected. The mechanism for this generalized effect of fatty acids on solute absorption is uncertain, possibly nonspecific, and might be related to mucosal damage and altered mucosal permeability induced by these agents.

2658 CALCIUM TRANSPORT IN DISPERSED ACINAR CELLS FROM RAT PANCREAS.

(Eng.) Gardner, J. D.; Hahne, W. F. (Bldg. 10, Rm. 9D-15, Natl. Inst. Health, Bethesda, MD 20014). *Biochim. Biophys. Acta* 471(3):466-476; 1977.

Studies were carried out to elucidate the basis for the discrepancy between the results of one study in which cholecystokinin and cholinergic agents were found to increase uptake of ^{45}Ca by dispersed acinar cells from rat pancreas, and results of other studies in which cholecystokinin and cholinergic agents did not alter or cause a slight decrease in ^{45}Ca uptake by pancreatic acinar cells. In the present study, increased uptake of ^{45}Ca by acinar cells incubated with cholecystokinin occurred only in cells washed with iced, 160 mM choline chloride. This increased uptake reflected increased cellular uptake of radioactivity from the wash solution but not from the incubation medium. Cholecystokinin had no effect on uptake of ^{45}Ca by cells washed with 160 mM choline chloride, containing 5 mM ethylenediaminetetraacetate, or by cells washed with Krebs-Ringer bicarbonate. Furthermore, cells washed with 160 mM choline chloride accumulated a substantial amount of ^{45}Ca from the wash solution, and this accumulation was increased in cells that had been preincubated with cholecystokinin. Cells washed with Krebs-Ringer bicarbonate did not take up ^{45}Ca from the wash solution.

2659 INTESTINAL OSMOLALITY AND CARBOHYDRATE ABSORPTION IN RATS TREATED WITH POLY-

MERIZED GLUCOSE. (Eng.) Daum, F.; Cohen, M. I.; McNamara, H.; Finberg, L. (North Shore Univ. Hosp., 300 Community Drive, Manhasset, NY 11030). *Pediatr. Res.* 12(1):24-26; 1978.

The intestinal osmolal physiology and absorption of comparable preparations of polymerized glucose and of glucose were evaluated in isolated segments of rat duodenum. The acute rise in the osmolality of the succus entericus after 5% polymer injections (298 mOsm/kg at 3 min, 311 mOsm/kg at 30 min) was significantly less than that noted after 5% glucose (387 mOsm/kg at 3 min, 351 mOsm/kg at 30 min). At 60 min, a steady state had been established, and no significant difference was found. Injections of 10% polymer were superior to those of 10% glucose, as they also produced a lower luminal osmolality (351 mOsm/kg versus 427 mOsm/kg at 30 min). Luminal polyethylene glycol concentrations revealed comparable increases in intraluminal water content after 10% polymer and 5% glucose (22% versus 25% at 30 min) injections. After polymer injections, four times as much glucose was present in the mucosa as in the succus, whereas after 5% glucose injections, a high concentration of glucose remained in the succus. These results indicate that polymer solutions produce lower luminal osmolality than glucose solutions of similar weight. In addition, enhanced glucose absorption by the mucosal cell is suggested in animals injected with polymer. Polymerized glucose should, therefore, provide twice the calories of glucose without a disparate increase in the intestinal osmolality and intraluminal diffusion of extracellular water. Because of these properties, such a polymer may be useful in the p.o. nutritional rehabilitation of neonates and infants with diarrhea.

2660 RATES AND MECHANISMS OF GLUCOSE, GALACTOSE, AND XYLOSE ABSORPTION IN MAN IN VIVO. (Eng.) Cook, G. C. (Hosp. for Tropical Diseases, 4 St. Pancras Way, London NW1 OPE, England). *Scand. J. Gastroenterol.* 12(6):733-737; 1977.

Jejunal absorption rates of glucose, galactose, and xylose were determined consecutively in six Arab subjects *in vivo*. A double-lumen tube perfusion technique was used, and the perfusion solutions contained 200 mM of each monosaccharide. The mean xylose absorption rate (0.63 mmol/30 cm jejunum/min) was significantly lower than that for glucose ($p<0.001$) and galactose ($p<0.001$). To investigate evidence that glucose and xylose share the same jejunal transfer mechanism, their absorption rates when given alone and together, at high concentrations, were determined in six other Arabs; perfusion solutions contained 200 mM glucose, 100 mM xylose, and 200 mM glucose plus 100 mM xylose. The rates of glucose and xylose absorption were not significantly influenced by the other monosaccharide. This study does not confirm the existence of a common transfer mechanism. A significant correlation between absorption rate of glucose and the weight of xylose excreted after a 25 g p.o. load ($p<0.05$) was demonstrated.

2661 PUROMYCIN INHIBITION OF CHOLESTEROL ABSORPTION IN THE RAT. (Eng.) Vahouny, G. V.; Ito, M.; Blendermann, E. M.; Gallo, L. L.; Treadwell, C. R. (George Washington Univ., Sch. Medicine and Health Sciences, Washington, DC 20037). *J. Lipid Res.* 18(6):745-752; 1977.

The effect of puromycin on intestinal cholesterol absorption was studied in rats with indwelling catheters in the left thoracic lymphatic duct. Puromycin administration (15 mg, i.p., over 9 hr) to female Wistar rats produced a marked depression of cholesterol absorption (from 23.5% of administered dose in controls to 7.5% in treated rats) under conditions where the absorption of simultaneously administered fatty acid was also dramatically inhibited (40% that of controls). The same treatment of male rats also produced a significant depression in cholesterol absorption (14% of administered dose in treated animals), but was without effect on absorption of the fatty acid. Despite the depressions of lipid absorption in puromycin-treated animals, there was no accumulation of either cholesterol or fatty acid in the intestinal mucosa of either sex. Actinomycin D treatment (1 mg/kg) of fasting male and female rats (receiving constant infusions of saline) had no effect on the rate of lymph production. This finding suggests that altered lymph production was not responsible for the depressed lipid absorption observed in fed animals treated with protein synthesis inhibitors. The selective inhibition of cholesterol absorption in male rats also precludes the possibility that the major effect of the inhibitor is on delayed gastric emptying.

2662 INHIBITION OF FOLATE ENZYMES BY SULFASALAZINE. (Eng.) Selhub, J.; Dhar, G. J.; Rosenberg, I. H. (Univ. Chicago, Pritzker Sch. Medicine, Chicago, IL 60637). *J. Clin. Invest.* 61(1):221-224; 1978.

To further explore the mechanism of sulfasalazine action, the interaction of the drug with the folate recognition site was tested with three enzymes: dihydrofolate reductase, methylenetetrahydrofolate reductase, and serine transhydroxymethylase, each catalyzing a reaction involving a different folate derivative. Each of these enzymes was inhibited by sulfasalazine in the same concentration range as that previously observed to inhibit intestinal folate transport (0.4-1.0 mM); the kinetic data were consistent with a competitive mode of inhibition. Specificity of inhibition was demonstrated by the finding that the reduction of the pteridine ring of pteroylheptaglutamic acid by dihydrofolate reductase was subject to inhibition, whereas the hydrolysis of the γ-glutamyl peptide side chain by chicken pancreas conjugase was not affected. These results suggest that sulfasalazine interferes with a folate recognition site that is common to these enzymes and to the intestinal transport system. Sulfasalazine, therefore, has certain properties of an antifolate drug.

2663 EFFECT OF FOLATE DEFICIENCY AND ETHANOL INGESTION ON INTESTINAL FOLATE ABSORPTION. (Eng.) Racusen, L. C.; Krawitt, E. L. (Dept. Medicine, Univ. Vermont, Burlington, VT 05401). *Am. J. Dig. Dis.* 22(10):915-920; 1977.

The effects of folate deficiency, generalized malnutrition, and alcohol ingestion on jejunal transport, mucosal uptake, and reduction of folic acid were evaluated in male Sprague-Dawley rats. As measured by an everted gut sac technique, a folate-deficient diet fed *ad libitum* did not alter transport of mucosal uptake of folate. Partial starvation, which was produced in rats pair-fed with animals ingesting ethanol (20% in drinking water, 2 weeks), increased jejunal folate transport and mucosal uptake in animals ingesting either a folate-deficient or control diet (5.5 mg folate/kg diet). Ethanol ingestion by rats consuming folate-deficient or control diets resulted in transport and mucosal uptake rates intermediate in value compared to those from *ad libitum* fed and pair-fed groups. No differences in reduction of folic acid were found. These results suggest that folate depletion and ethanol ingestion, alone or in combination, do not affect the ability of the rat jejunum to transport folate, but that partial starvation results in an increase in folate transport activity.

2664 A pH-DEPENDENT, CARRIER-MEDIATED TRANSPORT SYSTEM FOR THE FOLATE ANALOG, AMETHOPTERIN, IN RAT JEJUNUM. (Eng.) Strum, W. B. (10666 N. Torrey Pines Rd., La Jolla, CA 92037). *J. Pharmacol. Exp. Ther.* 203(3):640-645; 1977.

To investigate the mechanism of intestinal folate transport, transport of the folate analog, amethopterin, was studied in the rat using everted intestinal sacs and radiolabeled drug. After an initial lag period, the transport rate for amethopterin (0.5 μM) was linear for 60 min with a rate of 8.7 pmol/min/sac at pH 6.0 and 1.36 pmol/min/sac at pH 7.4. Chromatography confirmed that amethopterin was not altered after transport from the mucosa to the serosa. At pH 6.0, the transport system was saturable with a K_m of 2.8 μM and V_{max} of 66 pmol/min/sac; at pH 7.4, the system was not saturable. Accumulation of amethopterin (0.1 μM) against a chemical gradient was observed in jejunal, but not ileal, sacs and was pH dependent. Transport inhibition at pH 6.0 was produced by hydroxylamine, azide, fluoride, dinitrophenol, iodoacetate, and *p*-chloromercuriphenylsulfonate treatment, and by the absence of oxygen; this effect was not observed at pH 7.4. The transport of amethopterin was also inhibited by folate, 5-formyltetrahydrofolate, and 5-methyltetrahydrofolate. The inhibition constant for folate (K_i=2.6 μM) was similar to the K_m value for amethopterin transport. Inhibition of amethopterin transport by folate was competitive, as shown by the effect of various concentrations of folate on the transport rate of two different concentrations of amethopterin. Of the two reduced compounds tested, 5-formyltetrahydrofolate (K_i=2.0 μM) was a slightly more effective inhibitor than 5-methyltetrahydrofolate (K_i=3.3 μM). Additional analysis of the inhibitory process was obtained by determining the effect of 10 mM iodoacetate and 50 μM folate at pH 5.5 to 7.5; the response was observed to be pH-dependent with a maximal effect at pH 6.0. These data are consistent with a pH-dependent, carrier-mediated transport system for the folate analog, amethopterin, in the rat jejunum.

2665 EFFECT OF SYSTEMIC BACTERIAL INFECTION ON ABSORPTION RATES OF L-HISTIDINE AND GLYCYLGLYCINE FROM THE HUMAN JEJUNUM IN VIVO. (Eng.) Cook, G. C. (Hosp. Tropical Diseases, 4 St. Pancras Way, London, NW1 OPE, England). *Am. J. Clin. Nutr.* 30(2):1994-1998; 1977.

Jejunal absorption rates of L-histidine (from a 100 mM solution) and glycylglycine (from a 50 mM solution) were determined with a double-lumen tube perfusion system *in vivo* in six men with acute bacterial pneumonia (infection group) and six controls with no clinical evidence of a bacterial infection. The mean rate of histidine absorption was significantly higher in the infection group (0.795 ± 0.044 mmol/30 cm jejunum/min) compared with the control group (0.637 mmol/30 cm/min, $p<0.05$), but mean rates for glycine absorption from glycylglycine were not significantly different. During the glycylglycine infusions, the luminal disappearance rate of the intact peptide was significantly greater than the total glycine absorption rate ($p<0.001$). The correlation between individual histidine and glycylglycine absorption rates was significant (r=+0.645, $p<0.05$). This correlation probably occurs because, after intracellular hydrolysis and efflux to the lumen, some glycylglycine is reabsorbed as free glycine by the amino acid transfer mechanism, and the rate of that reabsorption has previously been shown to be increased in subjects with systemic bacterial infections.

MOTILITY

2673 VAGAL CONTROL OF LOWER ESOPHAGEAL SPHINCTER MOTILITY IN THE CAT. (Eng.) Gonella, J.; Niel, J. P.; Roman, C. (Institut de Neurophysiologie et Psychophysiologie, 31 Chemin Joseph Aiguier, 13274 Marseille Cedex 2, France). *J. Physiol. (Lond.)* 273(1):647-664; 1977.

The effects of vagal efferent fiber stimulation on the smooth muscle of the lower esophageal sphincter were studied in anesthetized cats and in isolated and perfused organ. In both the longitudinal and circular muscle layers, vagal stimulation elicited two types of electromyographic (EMG) potentials: (a) excitatory junction potentials (EJPS) where there was a depolarization of the smooth muscle fibers and (b) inhibitory junction potentials (IJPS) where there was hyperpolarization of the smooth muscle fibers, often followed by a transient depolarization that could initiate spikes (postinhibitory rebound). EJPS gave rise to spike potentials inducing a contraction of the sphincter. Pure IJPS were observed after atropine treatment, which suppressed EJPS. Under these conditions, a long lasting vagal stimulation induced a long duration hyperpolarization concomitant with an opening of the lower esophageal sphincter followed after the cessation of stimulation by a powerful rebound leading to a strong contraction, which closed the sphincter. The results suggest the following conclusions. Preganglionic vagal fibers are cholinergic, and they activate intramural excitatory cholinergic neurons and intramural nonadrenergic inhibitory neurons (purinergic neurons). Preganglionic fibers leading to inhibition have a higher threshold than those leading to excitation. Both excitatory and inhibitory pathways are interconnected inside the intramural network. In particular, activation of intramural inhibitory neurons, by relaxing the esophagus orally to the lower esophageal sphincter, inhibits intramural excitatory neurons and subsequently blocks vagal excitatory responses. Two functions may be attributed to the vagal extrinsic innervation: (a) closure of the lower esophageal sphincter by maintaining the basal tone of the sphincter; this would imply that at rest the inhibitory control is supplanted by the excitatory one and (b) opening the sphincter during swallowing by suppressing the excitatory stimulus and reinforcing the inhibitory one.

2674 AN EXTRALUMINAL FORCE TRANSDUCER FOR RECORDING CONTRACTILE ACTIVITY OF THE GASTROINTESTINAL SMOOTH MUSCLE IN THE CONSCIOUS DOGS: ITS CONSTRUCTION AND IMPLANTATION. (Eng.) Itoh, Z.; Honda, R.; Takeuchi, S.; Aizawa, I.; Takayanagi, R. (Gunma Univ. Sch. Medicine, Maebashi, 371, Japan). *Gastroenterol. Jpn.* 12(4):275-283; 1977.

An extraluminal strain-gauge force transducer for the continuous long-term (more than 5 months) recording of contractile activity of the gastrointestinal smooth muscle in conscious experimental animals was constructed and tested in dogs. Since the transducer is sutured onto the outside of the gut, it does not interfere with the passage of contents in the gut. The transducer was demonstrated by using it to record 24-hr changes in motor activity in the gastric body and antrum of a conscious dog using a paper recording speed of 1 mm/min. The contractile activity pattern of the stomach consisted of two major components, digestive and interdigestive states. The digestive pattern was characterized by continuous steady contractions in the antrum and no movements in the gastric body. The interdigestive pattern consisted of a period of strong contractions of short duration and long-lasting motor quiescence in the gastric body and antrum. When the contractile activity pattern of the stomach was examined using a slower recording speed, it was found that another motor pattern was present; this pattern was intermediate between the two major components of the stomach contractile activity pattern. The findings obtained with the extraluminal transducer were almost identical to changes of intraluminal pressure recorded with the use of a small balloon placed in the gastric antrum. A disadvantage of the extraluminal transducer is that it measures only muscle contractions, making it difficult to determine movements of intraluminal contents, especially in the digestive state.

2675 INTERACTION BETWEEN LONGITUDINAL AND CIRCULAR MUSCLE IN INTESTINE OF CAT. (Eng.)

Connor, J. A.; Kreulen, D.; Prosser, C. L.; Weigel, R. (Dept. Physiology, Univ. Illinois, Urbana, IL 61801). *J. Physiol. (Lond.)* 273(3):665-689; 1977.

The electrical activity of the circular and longitudinal muscle layers was studied in small intestinal segments of cats, and differences in the activities of these layers *in vivo* and *in vitro* were noted. Slow waves recorded from isolated longitudinal muscle averaged 13 mV and had slow rate of rise (0.04 V/sec), whereas recordings from intact segments showed the amplitude averaged 27 mV, and the rate of rise was more rapid (0.09 V/sec), often with a notch between the initial peak and the plateau. Membrane potentials of longitudinal muscle were similar in isolated and intact preparations (-66 mV). Resting potentials of circular muscle averaged -67 mV. Small bundles of circular muscle tested in the double sucrose gap produced activity in three categories, either spontaneously or in response to stimulation: fast spikes (50-200 msec duration), slow spikes (1-5 sec duration), and small graded responses. The duration of fast spikes was increased several-fold by the addition of 20 mM tetraethylammonium (TEA); the graded responses were converted to full-sized spikes by TEA. Treatment of circular muscle with calcium-free Krebs solution eliminated spikes, and, in intact preparations, reduced the amplitude and rate of rise of slow waves and eliminated the notch on slow waves. Current-voltage curves of longitudinal muscle showed delayed rectification in the depolarizing quadrant; similar curves of circular muscle showed anomalous rectification, i.e., a region where a very small current caused a large voltage change. Nonpolarized electrotonic coupling between longitudinal and circular layers indicates low-resistance pathways. Apparent space constants of longitudinal muscle were greater when attached to circular muscle than when isolated. It is concluded that small slow potentials originate rhythmically in longitudinal muscle, that these spread passively to circular muscle where a regenerative amplification occurs that depends on calcium conductance, and that the amplified slow waves spread back to the longitudinal layer. In the intact intestine, pacemaking is, therefore, separate from propagation, and the circular muscle provides the bulk of depolarizing current for propagation.

2676 EFFECT OF SUBSTANCE P ON INTESTINAL MUSCLE. (Eng.)

Yau, W. M. (Sch. Medicine, Southern Illinois Univ., Carbondale, IL 62901). *Gastroenterology* 74(2, Part 1):228-231; 1978.

The mode of action of synthetic substance P on small intestinal motility was investigated *in vitro* in female guinea pigs. Substance P had a major stimulating effect on the intestine by eliciting mechanical contraction and bursts of spike potentials. On a molar basis, substance P was 1.6 x 10^3 times more potent than acetylcholine. Unlike cerulein, the effects of which were mediated through the release of acetylcholine from the enteric plexuses, the site of action of substance P appeared to be directly on the muscle cells because its effects were resistant to atropine, tetrodotoxin, and Lioresal. These data strongly suggest a possible physiological role of substance P in the modulation of intestinal longitudinal muscle motor activity.

2677 EFFECTS OF SOME GASTROINTESTINAL HORMONES ON TWO MUSCLE LAYERS OF DUODENUM. (Eng.)

Anuras, S.; Cooke, A. R. (Veterans Admin. Hosp., Iowa City, IA 52242). *Am. J. Physiol.* 234(1): E60-E63; 1978.

The effects of gastrointestinal hormones on the longitudinal and circular muscle of opossum and cat duodenum were studied, to determine whether the two muscle layers respond differently to various stimuli. The duodena were cut into strips 2 mm wide and 2-2.5 cm long. Strips cut in the oral-caudal axis were called longitudinal strips; those cut at 90 degrees to that axis were called circular strips. Cholecystokinin (CCK, maximum amplitude of contraction achieved at 5 x 10^{-9} M) and cerulein (2 x 10^{-7} M) stimulated phasic contractions of circular muscle of opossum duodenum, but had no effect on the longitudinal muscle. The effect of CCK was not blocked by tetrodotoxin (10^{-7} M), indicating a direct muscle stimulation. CCK (10^{-8}, 10^{-7}, and 2.5 x 10^{-7} M) had no effect on either muscle layer of the cat duodenum. In opossum duodenum, vasoactive intestinal peptide (10^{-7} M) raised tension in longitudinal muscle by 1 g but reduced tension in circular muscle by 0.8 g. Glucagon (10^{-5} M) slightly reduced tension in both longitudinal and circular muscle of opossum duodenum. It also inhibited contractions of circular muscle caused by acetylcholine. Pentagastrin (10^{-7}, 10^{-6}, and 10^{-5} M) and secretin (10^{-8}, 10^{-7}, 10^{-6}, and 4 x 10^{-5} M) had no effect on either muscle layer in either species. These findings suggest that the circular and longitudinal muscle layers of the duodenum respond differently to at least some gastrointestinal hormones. Also, there is species variation in response to gastrointestinal hormones.

2678 INFLUENCE OF PYRIDYLISATOGEN TOSYLATE ON CONTRACTIONS PRODUCED BY ATP AND BY PURINERGIC STIMULATION IN THE TERMINAL ILEUM OF THE GUINEA-PIG. (Eng.)

Kazic, T.; Milsavljevic, D. (Dept. Pharmacology, Medical Faculty, 11000 Beograd, P.O. B 662, Yugoslavia). *J. Pharm. Pharmacol.* 29(9): 542-545; 1977.

The effect of 2-2'pyridylisatogen tosylate (PIT) on contractions produced by ATP and by purinergic stimulation was investigated in terminal segments of ileum isolated from guinea pigs. PIT did not antagonize the excitatory effects of exogenous ATP and of purinergic stimulation of the terminal guinea pig ileum. PIT (0.5-2.5 μM) potentiated the ATP-induced contractions and also the contractions produced by potassium chloride, although the potentiation could not be related to the dose in every experiment. The responses to norepinephrine, epinephrine, and histamine were slightly inhibited. PIT also potentiated the contractions produced by electrical stimulation of intramural purinergic nerves when either an alternate or uniform stimulation pattern was used. These results, in which the preparation is contracted by ATP, are opposite to those obtained with PIT on the taenia caeci, which is relaxed by ATP. This finding raises a question of duality or plurality of receptors for ATP.

2679 CONTROL OF GASTRIC EMPTYING: INTERACTION OF THE VAGUS AND PYLORIC ANTRUM.

(Eng.) Yamagishi, T.; Debas, H. T. (Dept. Surgery, Univ. British Columbia, 700 West 10th Ave., Vancouver, British Columbia V5Z 1L5, Canada). *Ann. Surg.* 187(1):91-94; 1978.

To investigate the interaction of the vagus and the pylorus in the control of gastric emptying, the gastric emptying of liquids and solids was evaluated in 10 dogs with gastric fistula before and after either truncal vagotomy, antrectomy, or pyloroplasty. In subsequent operations, the vagotomy group underwent either antrectomy or pyloroplasty, and the antrectomy and pyloroplasty groups were vagotomized. Vagotomy significantly inhibited the emptying of both liquids and solids ($p<0.001$) when the pyloric antrum was intact. When the antropyloric mechanism was removed by antrectomy, the effect of vagotomy was to accelerate the emptying of liquids ($p<0.05$) but to impair the emptying of solids ($p<0.001$). After pyloroplasty, vagotomy markedly accelerated the emptying of liquids but had little effect on the emptying of solids. Neither antrectomy nor pyloroplasty had any significant effect on the emptying of solids. Pyloroplasty caused minor acceleration of emptying of liquids while antrectomy had no effect. These data show that, after vagotomy, the pylorus acts as a major obstruction to gastric emptying of both liquids and solids.

2680 VAGALLY INDUCED GASTRIC ANTRAL CONTRACTIONS AND GASTRIC EMPTYING OF A LIQUID TEST MEAL.

(Eng.) Carr, D. H.; Brooks, F. P. (Dept. Physiology and Anatomy, Massey Univ., Palmerston North, New Zealand). *Q. J. Exp. Physiol.* 63(1): 49-58; 1978.

The emptying of a liquid test meal from the stomach was studied during, and in the absence of, electrical stimulation of cut ends of a thoracic branch of the vagus in anesthetized cats. The test meal (154 mM NaCl and 30 mg/l phenol red) was measured by collecting effluent from a duodenal fistula over a 30-min period. The stomach emptied about 60% of the meal under control conditions compared with over 90% during efferent stimulation of the vagus. The increased volumes emptied during efferent stimulation were not accounted for by gastric acid secretion. Coincident with the vagally evoked antral contractions, there was a gush of liquid from the duodenal cannula. Afferent vagal stimulation resulted in an initial marked delay of emptying followed by an acceleration so that the volume emptied after 30 min was similar to that in control experiments. These experiments show that antral contractions, evoked by efferent vagal stimulation, accelerate gastric emptying of a liquid test meal.

2681 THE INFLUENCE OF GRADED DISTENSION AND CARBACHOL ON THE MOTOR RESPONSE TO CHOLECYSTOKININ IN ISOLATED GUINEA-PIG ANTRUM AND FUNDUS.

(Eng.) Gerner, T.; Haffner, J. F. W. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 12(6):745-749; 1977.

The effect of graded distention on the motor response to cholecystokinin (0.38 U/ml) and acetylcholine (10^{-3} M) in guinea pig antral and fundal pouches was investigated. Using a balloon technique, the pouches were increased in diameter by one-tenth of the initial diameter in each of four steps. At the concentrations used, both cholecystokinin and acetylcholine invariably stimulated motor activity. The increase mainly consisted of increased amplitude of rhythmic activity in the antrum and of increased basal pressure in the fundus. The responses to acetylcholine were consistently more pronounced than those to cholecystokinin. Distention had the most marked effect on basal pressure, but it also increased spontaneous pressure amplitude and enhanced the peak responses to cholecystokinin and acetylcholine. When the alterations in pressure were converted into wall tension the increase became even more marked. Changes in both spontaneous activity and drug responses were statistically significant ($p<0.05$) compared with undistended controls, and both spontaneous activity and drug responses reached a maximum when the pouch diameter was increased by 1.2-1.3 times its original diameter. Carbachol at concentrations of 10^{-8} to 10^{-4} M also increased rhythmic activity in the antrum and basal pressure in the fundus in a manner similar to that of cholecystokinin and acetylcholine. Prestimulation with carbachol 10 min before each addition of cholecystokinin resulted in an additive effect at the lowest carbachol concentrations (10^{-8} and 10^{-7} M); however, the response to cholecystokinin markedly declined after prestimulation with higher carbachol concentrations. The results indicate that the increased response to cholecystokinin after distention is due to increased smooth muscle stretch.

2682 EFFECT OF PENTAGASTRIN INFUSION ON GASTRIC EMPTYING RATE OF SOLID FOOD IN MAN.

(Eng.) MacGregor, I. L.; Wiley, Z. D.; Martin, P. M. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Am. J. Dig. Dis.* 23(1):72-75; 1978.

The effect of i.v. pentagastrin (4 μg/kg/hr) on the rate of gastric emptying of solid food was studied in six normal men. A meal consisting of one ^{99m}Tc-tagged chicken liver mixed with beef stew and taken with 200 ml of water was followed on its passage through the gastrointestinal tract by intermittent scanning with a gamma camera. The rate of the linear gastric emptying pattern was slowed by pentagastrin in every subject. The pH and titratable acidity of the gastric contents were similar in the pentagastrin and the control infusions. Neutralization of the gastric contents with bicarbonate in the pentagastrin studies did not alter gastric emptying rates. The results indicate that pentagastrin slows gastric emptying of solid food in man by an effect other than acid secretion.

2683 RELAXATIONS OF GUINEA-PIG FUNDIC STRIP BY ADENOSINE, ADENINE NUCLEOTIDES AND ELECTRICAL STIMULATION: ANTAGONISM BY THEOPHYLLINE AND DESENSITIZATION TO ADENOSINE AND ITS DERIVATIVES.

(Eng.) Okwuasaba, F. K.; Hamilton, J. T.; Cook, M. A. (Dept. Pharmacology, Univ. Western Ontario, London, Ontario N6A 5C1, Canada). *Eur. J. Pharmacol.* 46(3):181-198; 1977.

The effect of theophylline on relaxations of guinea pig fundic strips elicited by stimulation of noncholinergic, nonadrenergic nerves was compared to the effects of exogenously added drugs. In addition, the ability to desensitize the tissue in the presence of adenosine and related nucleotides was investigated to assess the role of the drugs as possible intramural transmitters. Adenosine and related compounds produced a concentration-dependent relaxation of the fundic strips in nontreated preparations and in preparations treated with atropine, tetrodotoxin (TTX), guanethidine, reserpine, or 6-hydroxydopamine (6-OH-DA). The relative potencies in descending order were ATP$\geq$ADP$>$adenosine. Theophylline (THEO) at low concentrations (25-75 μM) selectively antagonized the inhibitions produced by ATP, ADP, and adenosine without antagonizing those due to norepinephrine (NE), isoproterenol (ISO), and papaverine (PAPAV). Schild plots yielded apparent pA_2 values for THEO of 1.4×10^{-5} M, 1.8×10^{-5} M, and 2.8×10^{-5} M for ATP, ADP, and adenosine, resp., with slopes that were not significantly different ($p>0.05$). These results suggest competitive antagonism. Theophylline was a more specific antagonist of the relaxations induced by the purines than were compounds such as quinidine, phentolamine, or 2,2'-pyridylisatogen (PIT). In fundic strips pretreated with atropine (1×10^{-7}-5×10^{-7} M), transmural or periarterial nerve stimulation produced relaxations that were frequency-dependent. The effects of periarterial nerve stimulation were abolished by phentolamine plus propranolol, by guanethidine, by bretylium, by TTX, and by pretreatment with reserpine or 6-OH-DA. The responses to transmural nerve stimulation were abolished only by TTX. The relaxations induced by transmural nerve stimulation were reduced or abolished by THEO, whereas those produced by periarterial nerve stimulation were not affected. Theophylline was more selective than quinidine or phentolamine in blocking such responses. Exposure of the tissues to high concentrations of ATP, ADP, or adenosine caused tachyphylaxis to the relaxations induced by the purines as well as those to transmural nerve stimulation, while the responses to NA, ISO, PAPAV, or periarterial nerve stimulation were either augmented or unaffected. The effects of desensitization were reversible. This finding suggests that the response to transmural nerve stimulation may be due to neural release of adenosine or a related compound. An adenine nucleotide or nucleoside released from nerves might have a physiological function in the "receptive relaxation" of the stomach following stimulation of the pharynx and upper esophagus by passage of a bolus of food.

2684 EFFECT OF VASOACTIVE INTESTINAL POLYPEPTIDE ON GALLBLADDER SMOOTH MUSCLE IN VITRO.

(Eng.) Ryan, J. P.; Ryave, S. (Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *Am. J. Physiol.* 234(1):E44-E46; 1978.

The effect of vasoactive intestinal polypeptide (VIP) on basal tension and on tension induced by octapeptide of cholecystokinin (OP-CCK) was examined with guinea pig gallbladder smooth muscle strips *in vitro*. VIP (1.0-200.0 ng/ml) alone produced dose-related decreases in resting tension, and antagonized spontaneous contractile activity where present. In combination with OP-CCK (0.1-10.0 ng/ml), VIP decreased the expected contractile response. The degree of antagonism depended upon the concentrations of OP-CCK and VIP. VIP had no effect on acetylcholine-induced contractions. It is proposed that VIP can affect gallbladder motor activity by decreasing smooth muscle tone and by antagonizing cholecystokinin. These findings support the proposal that gallbladder motor function may depend upon the action and interaction of the gastrointestinal hormones.

2685 INFLUENCE OF THE REMOVAL OF EXTERNAL K ON TONUS AND DRUG-INDUCED CONTRACTIONS OF THE ISOLATED RAT ILEUM, PARTICULARLY IN RELATION TO Ca.

SECRETION AND METABOLISM

2712 HEPTADECAPEPTIDE GASTRIN IN THE VAGAL NERVE. (Eng.) Uvnas-Wallensten, K.; Rehfeld, J. F.; Larsson, L. I.; Uvnas, B. (Karolinska Institutet, Stockholm, Sweden). *Proc. Natl. Acad. Sci. USA* 74(12):5707-5710; 1977.

Studies were carried out to determine whether heptadecapeptide gastrin is present in specimens from the main trunks of the cervical, thoracic, and abdominal vagi of dogs and cats and in specimens from the abdominal vagus of humans. Immunoreactive gastrin was present in vagal nerves from cats, dogs, and humans. The abdominal portion of the vagus contained gastrin in amounts ranging from 16 to 273 pmol/g of nerve tissue (wet weight). The thoracic and cervical portion of the vagi contained only minute amounts of gastrin. Gel chromatography of extracts of human, canine, and feline abdominal vagi monitored by region-specific antisera against heptadecapeptide gastrin and triacontatriapeptide cholecystokinin revealed that the vagal gastrin immunoreactivity predominantly consisted of heptadecapeptide gastrin. In addition, the vagi contained small amounts of the NH_2-terminal tridecapeptide gastrin fragment as well as of the putative biosynthetic gastrin precursors, components I and II. No cholecystokinin-like molecules were demonstrable. Immunocytochemical studies demonstrated gastrin-containing nerves in the intestinal wall. The nerves were most numerous in the large and distal small intestine. These findings suggest that heptadecapeptide gastrin may represent a new vagal neurotransmitter.

SECRETION AND METABOLISM

Stomach

2720 CONCENTRATIONS OF GASTRIN AND SECRETIN IN THE ALIMENTARY TRACT OF THE CAT. (Eng.) Miller, T. A.; Llanos, O. L.; Swierczek, J. S.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Surgery* 83(1):90-93; 1978.

The distribution of gastrin and secretin was determined from the esophagogastric junction to the ileocecum in the cat. The total content and concentration of each of these hormones in mucosal extracts taken from the gastric fundus, gastric antrum, proximal and distal duodenum, proximal and distal jejunum, and ileum were measured with specific radioimmunoassays. The gastric antrum contained the highest concentration of gastrin (31,686.2 ± 8,375.7 ng), but appreciable amounts also were found in the duodenum (642.7 ± 184.6 and 1,074.0 ± 127.7 ng in proximal and distal regions, resp.). The highest concentrations of secretin were found in the duodenum (293.3 ± 43.4 and 1,323.7 ± 188.6 ng in proximal and distal regions, resp.), but impressive quantities were measured in the jejunum (710.2 ± 256.9 and 435.2 ± 90.8 ng in proximal and distal regions, resp.). The role of extra-antral gastrin and of those stores of secretin beyond the proximal duodenum (where the pH probably never falls to levels associated with release of secretin) currently are unknown.

2721 SECRETORY STATE OF GASTRIC MUCOSA AND ITS RESISTANCE TO ASPIRIN INJURY. (Eng.) Porterfield, G. N.; Cheung, L. Y. (Washington Univ. Sch. Medicine, 4960 Audubon Ave., St. Louis, MO 63110). *Am. J. Surg.* 135(1):115-119; 1978.

The influence of the secretory status on gastric mucosal tolerance to aspirin injury was assessed in a canine *ex vivo* model, which provided two segments of mucosa supplied by a single vascular pedicle in the same dog. Acid secretion was stimulated by the i.v. infusion of histamine (1 µg/kg/min) in one mucosa, whereas the secretory response to histamine was significantly impaired by topical treatment with 16,16-dimethylprostaglandin E_2 (25 µg) in the other. The secreting mucosa exhibited a twofold greater blood flow than the inhibited mucosa. Exposure of both mucosae to 20 mM aspirin for 30 min resulted in the appearance of small multiple superficial erosions. The degree of mucosal injury was not significantly different between the secreting and inhibited mucosae. The extent of mucosal damage was similar to that seen when aspirin in acid was placed on resting mucosa in the same model. These data do not support the hypothesis that histamine-stimulated acid secretion and accompanying increase in gastric mucosal blood flow protects against aspirin injury.

2722 EFFECT OF Ca^{2+}, Mg^{2+}, NaN_3, CHOLINERGIC AGENTS, AND GASTROINTESTINAL HORMONES ON THE GUANYLATE CYCLASE FROM GUINEA PIG GASTRIC MUCOSA. (Eng.) Griessen, M. (Hopital Cantonal, 1211 Geneve 4, Switzerland). *Gastroenterology* 74(2, Part 1):263-270; 1978.

The kinetic properties of gastric mucosal guanylate cyclase were examined in the guinea pig gastric mucosa, and the possibility that choline esters and pentagastrin increase the cyclic GMP production in the guinea pig gastric mucosa was tested. Guanylate cyclase in the fundic mucosa occurred in two enzymatic forms: a "soluble" form and a particulate form. The mean basal activity of the soluble fraction measured in the presence of 300 µM guanosine-5'-triphosphate and 5 mM $MnCl_2$ was 72.6 ± 5.3 pmol cyclic GMP/mg protein/min. Guanylate cyclase activity was dependent on Mn^{2+}; it was increased by sodium azide (NaN_3), $CaCl_2$, cysteine, secretin, and cholecystokinin, but it was not influenced by gastrin, histamine, cholinergic esters, or prostaglandins E_1 and A_1. NaN_3 (1 mM) decreased the apparent K_m for $MnCl_2$ and potentiated the effects of $MgCl_2$. The activity of the particulate fraction represented about 14% of that of the supernatant fraction. The guanylate cyclase activity of that fraction was not modified by NaN_3, gastrin, cholinergic agents, secretin, or cholecystokinin. Cysteine inhibited its activity. These data do not support the hypothesis that cyclic GMP acts as a second messenger for the action of cholinergic agents and gastrin in the guinea pig gastric mucosa.

2723 GASTRIC MUCOSAL DAMAGE BY TAURINE AND GLYCINE CONJUGATES OF CHENODEOXYCHOLIC ACID.

(Eng.) Black, R. B.; Naylor, F.; Stenhouse, N. S. (Queen Elizabeth Hosp., Woodville, South Australia 5011, Australia). *Am. J. Dig. Dis.* 22(12):1106-1108; 1977.

To determine whether the greater bile acid-induced gastric mucosal damage seen at an acid pH is dependent upon the type of bile acid conjugation, pure 10 mM solutions of taurine and glycine conjugates of chenodeoxycholic acid were instilled into canine Heidenhain pouches. Solutions were prepared at pH 2, 4, and 8. The pH effect was confirmed, but only with respect to movement of Na^+ ion for taurine conjugates. The magnitude of the changes in ionic movements was much greater with pure bile acid solutions than that seen previously with whole bile. The greater damage seen below the pK_a of the bile acid conjugates suggests that its nonionized form is the more damaging.

2724 EFFECT OF PROTEOLYTIC ENZYMES ON THE BINDING OF COBALAMIN TO R PROTEIN AND INTRINSIC FACTOR: IN VITRO EVIDENCE THAT A FAILURE TO PARTIALLY DEGRADE R PROTEIN IS RESPONSIBLE FOR COBALAMIN MALABSORPTION IN PANCREATIC INSUFFICIENCY.

(Eng.) Allen, R. H.; Seetharam, B.; Podell, E.; Alpers, D. H. (Univ. Colorado Medical Center, Denver, CO 80262). *J. Clin. Invest.* 61(1):47-54; 1978.

To test the hypothesis that R protein acts as an inhibitor of cobalamin (Cbl) absorption and that pancreatic proteases are required to alter R protein and prevent such inhibition, the ability of R protein and intrinsic factor (IF) to compete for Cbl binding, and the ability of pancreatic proteases to alter this competition, were studied. Human salivary R protein bound Cbl with affinities that were 50- and 3-fold higher than those of human IF at pH 2 and 8, resp. Cbl bound to IF was transferred to an equal amount of R protein with half times of 2 and 90 min at pH 2 and 8, resp., and within several hours the respective ratios of R protein-Cbl/IF-Cbl of 50 and 2 were observed. Cbl bound to R protein was not transferred to IF at either pH 2 or 8. Incubation of R protein with pancreatic proteases at pH 8 led to a 150-fold decrease in its affinity for Cbl. Incubation of R protein-Cbl with pancreatic proteases led to complete transfer of Cbl to IF within 10 min. Gel filtration studies with R protein-^{57}Co-Cbl and ^{125}I-R protein showed that pancreatic proteases partially degraded R protein. Pancreatic proteases differed in their ability to effect these changes with trypsin>chymotrypsin>elastase. Pancreatic proteases did not alter IF in any of the parameters mentioned above. Pepsin failed to alter either R protein or IF. These studies suggest: (a) that Cbl is bound almost exclusively to R protein in the acid milieu of the stomach, rather than to IF; (b) that Cbl remains bound to R protein in the slightly alkaline environment of the intestine until pancreatic proteases partially degrade R protein and enable Cbl to become bound exclusively to IF; and (c) that the primary defect in Cbl absorption in pancreatic insufficiency is a lack of pancreatic proteases and a failure to alter R protein and effect the transfer to Cbl to IF. These studies also suggest that the partial correction of Cbl malabsorption observed with bicarbonate is due to neutralization of gastric HCl, since at slightly alkaline pH, IF can partially compete with R protein for the initial binding and retention of Cbl.

2725 INFLUENCE OF BETA RECEPTOR BLOCKADE ON PENTAGASTRIN-STIMULATED GASTRIC SECRETION.

(Ger.) Anschelwitsch, J.; Okun, K. (Therapeutische Hospitalklinik, Medizinische Institut Riga, Bulv. Padomju 12, Riga, USSR). *Dtsch. Z. Verdau. Stoffwechselkr.* 37(5/6):219-223; 1977.

The effect of beta receptor blockade by propranolol (4 mg, i.v.) on the gastric secretion induced by pentagastrin (6 µg/kg) was studied in 27 men aged 20-50 yr. They included healthy persons and patients with duodenal and gastric ulcers. Propranolol was administered immediately before pentagastrin. While pentagastrin alone reduced the pH of the gastric juice by 1.3-1.4 units, it had no pH-reducing effect during beta receptor blockade. Propranolol significantly reduced the stimulating effect of pentagastrin on gastric secretion; the volume of the gastric juice decreased by 50%, the hydrochloric acid content by 35%, the hydrochloric acid concentration by 23%, and the quantity of pepsin by 72%. The proteolytic enzyme secretion was 124.6 mg/hr following pentagastrin stimulation, and 72.2 mg/hr following pentagastrin stimulation under beta receptor blockade. The findings indicate the great significance of beta-adrenergic processes in the secretory effect of pentagastrin.

2726 EFFECT OF SUB-DIAPHRAGMATIC VAGOTOMY ON GASTRIC MUCOSAL MAST CELL POPULATION IN PYLORUS LIGATED RATS.

(Eng.) Ganguly, A. K.; Sathiamoorthy, S. S.; Bhatnagar, O. P. (Government Medical Coll., Surat-395 001, India). *Q. J. Exp. Physiol.* 63(1):89-92; 1978.

The role of the vagus in the development of experimental stress ulcers was assessed by studying the gastric mucosal mast cell population following subdiaphragmatic vagotomy in albino rats, 6 and 12 hr after pylorus ligation, or in control rats with a sham-vagotomy. Subdiaphragmatic vagotomy significantly increased the gastric mucosal mast cell population in both 6- and 12-hr groups (from 189 ± 9 cells/mm^2 gastric mucosa in controls to 269 ± 8 cells/mm^2 6 hr after ligation, $p<0.001$; from 129 ± 7 to 322 ± 10 cells/mm^2 12 hr after ligation, $p<0.001$). The results suggest that the vagal impulses act on the gastric mucosal mast cells causing their degranulation. Following vagotomy, the contents stay bound within the mast cells. The increase in the mast cell population 12 hr after pylorus ligation may have been due to the continuation of normal turnover of the mast cells in the gastric mucosa. The results do not support the conclusion that the vagal influence on mast cell population is similar throughout the gastrointestinal tract.

2727 THE PARATHYROID GLANDS IN EXPERIMENTALLY INDUCED HYPERGASTRINEMIA IN THE RAT. (Eng.) Grimelius, L.; Johansson, H.; Lundqvist, G.; Olazabal, A.; Polak, J. H.; Pearse, A. G. E. (Dept. Pathology, Univ. Uppsala, P.O. Box 553, S-751 22 Uppsala, Sweden). *Scand. J. Gastroenterol.* 12(6):739-744; 1977.

To determine the importance of hypergastrinemia in the development of hyperparathyroidism, the morphology of the parathyroids in male Sprague-Dawley rats with hypergastrinemia, induced by antral exclusion, was compared with that of glands from untreated rats and animals from which the main source of gastrin-17 was excluded by antral resection. Fourteen weeks after induction of hypergastrinemia, the volume of the parathyroids was significantly increased in comparison with that in controls ($0.001<p<0.01$), owing to hyperplasia of the parenchymal cells. Removal of the antral gastrin-producing capacity of the same duration was not accompanied by any significant changes in the parathyroids. These findings suggest that hypergastrinemia could be a stimulus for the development of hyperplasia of the parathyroids, and that it may be an etiological factor in the production of hyperparathyroidism.

2749 INTRACELLULAR DIVALENT CATION RELEASE IN PANCREATIC ACINAR CELLS DURING STIMULUS-SECRETION COUPLING. II. SUB-CELLULAR LOCALIZATION OF THE FLUORESCENT PROBE CHLOROTETRACYCLINE. (Eng.) Chandler, D. E.; Williams, J. A. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *J. Cell Biol.* 76(2):386-399; 1978.

Subcellular distribution of the divalent cation-sensitive probe chlorotetracycline (CTC) was observed by fluorescence microscopy in isolated mouse pancreatic acinar cells, dissociated rat hepatocytes, frog rod photoreceptors, and human RBC. In each cell type, areas containing membranes fluoresced intensely while areas containing no membranes (nuclei and zymogen granules) were not fluorescent. Cell compartments packed with rough endoplasmic reticulum or Golgi vesicles (acinar cells) or plasma membrane-derived membranes (rod outer segments) exhibited a uniform fluorescence. In contrast, cell compartments having large numbers of mitochondria (hepatocytes and the rod inner segment) exhibited a punctate fluorescence. Punctate fluorescence was prominent in the perinuclear and perigranular areas of isolated acinar cells during CTC efflux, suggesting that, under these conditions, mitochondrial fluorescence may account for a large portion of acinar cell fluorescence. Fluorometry of dissociated pancreatic acini, preloaded with CTC, showed that the application of the mitochondrial inhibitors antimycin A, NaCN, rotenone, or carbonyl cyanide *m*-chlorophenylhydrazone, or of the divalent cation ionophore A23187 (all agents known to release mitochondrial calcium) rapidly decreased the fluorescence of acini. In the case of mitochondrial inhibitors, this response could be elicited before but not following the loss of CTC fluorescence induced by bethanechol stimulation. Removal of extracellular Ca^{2+} and Mg^{2+} or the addition of EDTA also decreased fluorescence but did not prevent secretagogues or mitochondrial inhibitors from eliciting a further response. These data suggest that bethanechol acts to decrease CTC fluorescence at the same intracellular site as do mitochondrial inhibitors. This effect could be due to release of calcium from either mitochondria or another organelle that requires ATP to sequester calcium.

2750 IN VITRO ACTION OF BOMBESIN ON AMYLASE SECRETION, MEMBRANE POTENTIAL, AND MEMBRANE RESISTANCE IN RAT AND MOUSE PANCREATIC ACINAR CELLS: A COMPARISON WITH OTHER SECRETAGOGUES. (Eng.) Iwatsuki, N.; Petersen, O. H. (Univ. Dundee Medical Sch., Dundee DD1 4HN, Scotland). *J. Clin. Invest.* 61(1):41-46; 1978.

The effect of bombesin on the potential difference and resistance across the pancreatic acinar cell membrane was tested, and the effects were compared with those of other known stimulants. In addition, the dynamic profile of amylase output after bombesin and after acetylcholine (ACh) stimulation was compared. Bombesin caused depolarization of rat or mouse pancreatic acinar cell membrane, reduction of membrane resistance, and a steep rise in amylase output from superfused pancreatic fragments. These effects were similar to those previously described for acetylcholine, cholecystokinin, and gastrin. The dose-response curves for these three effects of bombesin were very similar, with effects being detectable at concentrations of about 30 pM and maximal effects at about 10 nM. The equilibrium potential for the membrane action of bombesin (the membrane potential at which bombesin did not cause any change in membrane potential) was -16 mV. Similar values for equilibrium potential were obtained with acetylcholine, cerulein, and pentagastrin. Bombesin in the higher dose range (10 nM) caused electrical uncoupling of acinar cells within an acinus, i.e., a marked increase in junctional membrane resistance. Similar uncoupling effects were observed after acetylcholine, cerulein, and pentagastrin stimulation. Bombesin acts on the pancreatic acinar plasma membrane in exactly the same way as acetylcholine and cholecystokinin-pancreozymin. The electrical uncoupling caused by stimulation is evidence for an increase in cytosol free calcium ion concentration.

2751 INHIBITORY EFFECT OF VARIOUS CYTOSTATICS AND CYCLOHEXIMIDE ON ACUTE EXPERIMENTAL PANCREATITIS IN RATS. (Eng.) Korbova, L.; Kohout, J.; Malis, F.; Balas, V.; Cizkova, J.; Marek, J.; *et al.* (Faculty General Medicine, Charles Univ., Prague, Czechoslovakia). *Gut* 18(11):913-918; 1977.

The effects of drugs that interfere with nucleic acid and protein syntheses on acute experimental pancreatitis were studied in male Wistar rats. Cycloheximide (0.25 mg/kg, s.c.), 5-azacytidine (4.85 mg/kg, s.c.), and 4-methoxybenzoyl-β-bromoacrylate (Cytembena, 2.0 mg/kg, s.c.) blocked the the development of experimental acute pancreatitis that was mediated by the interstitial administration of 5% bile solution into the pancreas *in vivo.* Six hours after drug treatment, the pathological changes, evaluated macroscopically or using histological sections of the pancreas, were significantly decreased. The drugs affected the amount of abdominal fluid and lowered its lipase activity (to 92%, 70%, and 70% of control for Cytembena, 5-azacytidine, and cycloheximide, resp.) and amylase activity (to 70%, 39%, and 64% of control, resp.). The fact that cycloheximide at low doses is relatively nontoxic may permit its clinical use in pancreatitis.

2752 EXPERIMENTAL SERUM PANCREATITIS: ITS PREVENTION WITH CYCLOPHOSPHAMIDE. (Ger.) Nizze, H. (Institut fur Allgemeine und Spezielle Pathologie, Bereich Medizin der Wilhelm-Pieck-Universitat Rostock, Stremplstr. 14, DDR-25 Rostock 1, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 37(5/6):241-246; 1977.

The prophylactic effect of cyclophosphamide (CP) on bovine serum-induced pancreatitis was studied in male AB colony mice. The animals were subdivided into 5 groups: group 1 received only bovine serum (1-2 x 0.3 ml/day, 26 total injections, i.p.); groups 2-4 received the same doses of bovine serum along with CP (4, 7, or 11 injections of 2 mg/day i.p.), while group 5 received CP only. The length of the treatment was 13 days. The animals of group 1 developed typical serum pancreatitis (pronounced interstitial lymphoplasmacytic pancreatitis with abundant peritoneal exudate and marked edema of the pancreas). Pancreatitis was not seen in the groups treated with CP. The findings indicate the prophylactic effect of CP against bovine serum-induced pancreatitis.

SECRETION AND METABOLISM

Hepatobiliary Tract

2778 STUDIES IN PHARMACOKINETICS AND TOLERANCE OF SUBSTANCES TEMPORARILY RETAINED IN THE LIVER BY MICROSPHERE EMBOLIZATION. (Eng.) Lindell, B.; Aronsen, K. F.; Nosslin, B.; Rothman, U. (Malmo General Hosp., Malmo, Sweden). *Ann. Surg.* 187(1):95-99; 1978.

The effect of microsphere embolization on the retention of inulin in the liver and on the toxicity of 5-fluorouracil (5-FU) was studied in male Wistar-Fur rats. The test substances were injected into the common hepatic artery through a retrograde catheter in the gastroduodenal artery. The injection of 0.5 ml of inulin (1.96 mg/ml aqueous solution) alone into the common hepatic artery produced a rapid elevation of the inulin blood concentration to a maximum of 50-55 µg/ml in 1 min; the concentration then rapidly fell to a level of about 10 µg/ml after 20 min. In contrast, when inulin was injected in combination with 42 x 10^4 degradable microspheres (19 ± 3.1 µm), the initial high peak in inulin blood concentration failed to appear, and the maximum blood concentration reached was only 20-25 µg/ml (p=0.01). The inulin concentration curve in the blood 20 min after the administration of inulin and microspheres was almost identical to the concentration found when inulin was injected alone. The injection of inulin with microspheres also led to a significantly (1% level) delayed excretion of inulin with urine; after 35 min, only 20% of the administered dose was found in the urine compared to 60% of the administered dose when inulin alone was injected. During the first 30 min after the injection of inulin and microspheres, the mean inulin concentration in the liver was raised by 42% (p=0.05) compared to when inulin was injected alone. Leukocytopenia, which resulted from the injection of 5-FU (300 mg/kg) alone into rats, was less marked when 5-FU was injected with 126 x 10^4 microspheres and was reversed at days 4 and 9 when a significantly (1% level) higher number of circulating WBC was found than when 5-FU was injected alone. The survival rate of rats given 5-FU alone was 22% compared with 75% when the drug was injected with microspheres (p=0.01). The increased tolerance to 5-FU was probably due to a prolonged first pass effect when the substance was temporarily retained in the liver by microsphere embolization.

2779 ENZYMOLOGY OF HUMAN ALCOHOL METABOLISM. (Eng.) Li, T. K. (No affiliation given). *Adv. Enzymol.* 45:427-483; 1977.

The properties of human liver alcohol dehydrogenase and aldehyde dehydrogenase are reviewed, their role in the physiology of alcohol elimination is assessed, and the findings compared with those from experimental animals. A specific affinity chromatography procedure has been developed that collectively purifies the many molecular forms of alcohol dehydrogenase in high yield. Studies with such preparations have revealed that the enzyme is a dimeric molecule of 85,000 daltons, containing 4 equivalents of zinc/mol protein. Several NAD^+-dependent, unspecific aldehyde dehydrogenases have been found in mammalian livers, some with high K_ms and other with low K_ms for acetaldehyde. The subcellular distribution of these enzymes has been determined, and the mitochondrial low-K_m aldehyde dehydrogenase has been identified as the principal enzyme responsible for acetaldehyde elimination in rats. A soluble form of aldehyde dehydrogenase, with a low K_m for acetaldehyde, has been isolated from human liver homogenates, but its subcellular location and role have not been established. It is postulated that the molecular heterogeneity of alcohol dehydrogenase in liver contributes to individual differences in alcohol-metabolizing capacity; the atypical phenotype of alcohol dehydrogenase has been postulated to underlie alcohol sensitivity. The decreased alcohol dehydrogenase activity seen in cirrhosis may reflect changes in the synthesis, degradation, metal binding, or activity of zinc metalloenzymes. The study of alcohol dehydrogenase and other zinc metalloenzymes in patients with alcoholic liver disease should aid in understanding the cellular pathology and pathogenesis of alcoholic cirrhosis.

2780 INCREASED HEPATIC OXYGENATION FOLLOWING ETHANOL ADMINISTRATION. (Eng.) Shaw, S.; Heller, E. A.; Friedman, H. S.; Baraona, E.; Lieber, C. S. (Bronx Veterans Admin. Hosp., 130 W. Kingsbridge Rd., New York, NY 10468). *Proc. Soc. Exp. Biol. Med.* 156(3):509-513; 1977.

The effects of ethanol on hepatic oxygenation were measured by hepatic vein catheterization in the baboon. Chronic alcohol administration (50% of total caloric intake for 1-4 yr) resulted in slightly lower oxygen tension in the hepatic vein, but not ischemia, when measured after an overnight fast when alcohol was no longer present in the blood. The i.v. administration of ethanol (1.75 g/kg) resulted in an increase in hepatic vein oxygen tension regardless of prior exposure to alcohol or the presence of liver disease. The increased oxygen tension after alcohol was associated with a marked increase in hepatic blood flow. These data in conjunction with the observation of progressive liver injury in the alcohol-fed animals support the concept that alcoholic liver injury can develop despite unimpaired hepatic oxygenation.

2781 PROBING THE ACTIVE SITE OF LIVER ALCOHOL DEHYDROGENASE. (Eng.) Dutler, H. (Laboratorium fur Organische Chemie, ETH Universitatstrasse 6, CH-8006 Zurich, Switzerland). *Biochem. Soc. Trans.* 5(3):617-620; 1977.

Kinetic and modeling studies designed to determine the active site of liver alcohol dehydrogenase are described. The reduction of racemic 2-, 3-, and 4-alkylcyclohexanones with methyl, ethyl, isopropyl, and tertiary-butyl alkyl groups was studied on a preparative scale and under conditions where the coenzyme NADH was continuously regenerated by auxiliary enzymes (glucose-6-phosphate dehydrogenase and aldolase). Product formation was followed by gas chromatography combined with determination of enantiomer composition by nuclear magnetic resonance spectroscopy of the α-methoxy-α-trifluoromethylphenylacetyl esters of the product alcohols. The kinetic method for determining at which position of the cyclohexanone ring an alkyl group leads to favorable or unfavorable intermolecular interactions with the enzyme involved reducing the pairs of enantiomeric alkylcyclohexanones to the four possible alcohols in each case. The kinetically obtained information was then compared with modeling study results to identify groups involved on the side of the active-site pocket of the enzyme. The active-site pocket, including the nicotinamide moiety of the coenzyme, was built with Kendrew-type models, and models of the alkylcyclohexanols formed as products were placed into the active-site pocket such that their hydroxyl oxygen atom appeared in the position where the water oxygen atom was observed in the apoenzyme. The alkylcyclohexanol models were allowed to change their orientation within geometric constraints until full agreement was achieved between the interactions observed in the model and those determined kinetically. In the resulting model, the cyclohexanol rings of all products were superimposed and therefore showed the same orientation relative to the nicotinamide moiety of the coenzyme. Excellent agreement between the modeling study and the kinetic studies was obtained, suggesting that the model of the enzyme-product complex discloses all of the interesting structural features of the enzyme-substrate complex.

2782 SERUM ENZYME ACTIVITIES IN RATS WITH CHRONIC LIVER DAMAGE. COMMUNICATION 2: EFFECT OF ALLYL ALCOHOL. (Ger.) Neubauer, J.; Schieke, S.; Schulz, I.; Skorka, G.; Bien, E. (Institut fur Pharmakologie und Toxicologie, Humboldt-Universitat zu Berlin, Berlin, E. Germany). *Pharmazie* 32(7):406-409; 1977.

The effect of a 20-week treatment with allyl alcohol (0.02 and 0.04 ml/kg/day in 1% and 2% aqueous solutions) on the activities of certain serum enzymes (SGOT, SGPT, glutamate dehydrogenase, lactate dehydrogenase, leucine aminopeptidase, and alkaline phosphatase) was studied in male Wistar rats aged 12-14 weeks at the beginning of the experiment. Allyl alcohol was administered by a probang; the animals received food and water *ad libitum*. The control animals received water only. Severe diarrhea with fatal outcome was observed in 4/42 animals treated with 0.04 ml/kg doses, but there were no visible changes in the other animals. Allyl alcohol caused a significant but transient increase in SGPT (from 28 IU/l to a maximum 53 IU/l after 4 weeks of treatment with the 0.02 ml/kg dose, and to 51 IU/l after 8 weeks of treatment with the 0.04 ml/kg dose) and in glutamate dehydrogenase activity (from 5.4 IU/l in the controls to 18.1 IU/l after 4 weeks of treatment with the 0.02 ml/kg dose, and to 26 IU/l after 8 weeks of treatment with the 0.04 ml/kg dose). The findings indicate the relevance of glutamate dehydrogenase determinations in the detection of liver damage in experimental animals.

2783 EFFECT OF GLUCOCORTICOIDS ON AMINO ACID TRANSPORT IN ISOLATED RAT HEPATOCYTES. (Eng.) Le Cam, A.; Freychet, P. (INSERM U-145, Faculte de Medecine [Pasteur], Chemin de Vallombrose, 06034 Nice Cedex, France). *Mol. Cell. Endocrinol.* 9(2):205-214; 1977.

The effects of glucocorticoids on neutral amino acid transport were studied in freshly prepared suspensions of isolated hepatocytes from adult rat. Cortisol and dexamethasone at 10 μM stimulated the active transport of α-aminoisobutyric acid by about 40% by increasing the influx. The onset of effect was preceded by a lag period of about 1 hr. Cortisol (ED_{50}≈2 μM) was 10-20 times less potent than synthetic analogs. Glucocorticoids increased the V_{max} of transport without affecting the K_m. Actinomycin D and cycloheximide virtually abolished this effect. The glucocorticoid effect involved predominantly the A system of transport. The effect was additive with that of glucagon, insulin, and catecholamines.

2784 INDIVIDUAL BILE ACIDS IN PORTAL VENOUS AND SYSTEMIC BLOOD SERUM OF FASTING MAN. (Eng.)

Ahlberg, J.; Angelin, B.; Bjorkhem, I.; Einarsson, K. (Serafimerlasarettet, S-112 83 Stockholm, Sweden). *Gastroenterology* 73(6):1377-1382; 1977.

The serum concentrations of cholic acid (C), chenodeoxycholic acid (CD), and deoxycholic acid (D) were determined, using a highly specific gas chromatographic-mass spectrometric technique, in peripheral venous and portal venous blood from 10 otherwise healthy patients undergoing elective cholecystectomy. The mean C content of the peripheral venous serum was 0.49 ± 0.16 μM; the mean CD and D contents were 1.55 ± 0.32 and 1.44 ± 0.57 μM, resp. Arterial serum, obtained from five of the subjects, did not show any differences in bile acid concentrations compared to venous serum. In contrast, the portal venous content of each bile acid was several-fold greater, 6.14 ± 1.20 μM of C, 8.40 ± 1.84 μM of CD, and 6.18 ± 2.27 μM of D. The hepatic uptake of C was estimated to be about 90%, whereas that of CD and D was lower, about 70%. This difference in hepatic uptake between the individual bile acids was reflected in the relative composition of the total bile acids, which was 30:39:31 (C:CD:D) in portal venous serum and 13:50:37 in peripheral serum. Compared to common duct bile obtained simultaneously, the portal vein contained a greater proportion of CD. It is suggested that the higher fasting level of CD compared to C in peripheral serum may result from the combination of a lower fractional hepatic extraction and a higher portal venous input to the systemic circulation.

2785 SERUM BILE ACID LEVELS: A COMPARTMENTAL MODEL FOR THE DYNAMICS OF THE ENTEROHEPATIC CIRCULATION. (Eng.)

Hoffman, A. F.; La Russo, N. F.; van Berge-Henegouwen, G. P. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 151-156; 1977.

A multicompartmental model is proposed for the hepatic part of the enterohepatic circulation of bile acids. The model postulates a well-mixed sinusoidal compartment, one constant fraction passes into the hepatocyte and the remainder enters the peripheral plasma compartment. The flux of any bile acid entering the peripheral plasma compartment at any moment is equal to (1-first pass hepatic clearance) x that bile acid flux to the liver. The total spillover of bile acids into the peripheral plasma compartment is the sum of the individual spillovers. This model explains why the level of serum bile acids in peripheral blood rises postprandially, why interruption of the enterohepatic circulation causes a fall in serum bile acids, and why fasting-state serum bile acids are enriched in chenodeoxycholic acid when compared to fasting-state biliary bile acids.

2786 INFLUENCE OF CHEMICAL STRUCTURE ON HEPATOCELLULAR UPTAKE OF BILE ACIDS. (Eng.)

Reichen, J.; Preisig, R.; Paumgartner, G. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 113-123; 1977.

The kinetics of uptake of ^{14}C-labeled cholic, taurocholic, and chenodeoxycholic acids were studied in the perfused rat liver by the multiple-indicator dilution technique. All three bile acids exhibited saturation kinetics. The maximal uptake velocity (V_{max}) was similar for the trihydroxy bile acids taurocholate (20.8 nmol/sec/g liver) and cholate (24.9 nmol/sec/g liver); it was only half this value for the dihydroxy bile acid, chenodeoxycholate (11.4 nmol/sec/g liver). The apparent half-saturation constant, K_m, was 100% higher for the unconjugated bile acid cholate (526 nmol/g liver) than for its conjugated analog, taurocholate (258 nmol/g); it was similar for chenodeoxycholate (236 nmol/g) and for taurocholate. It is assumed that the difference in the apparent K_m reflects intrinsic differences in the affinity of different bile acids for the hepatic carrier. The findings suggest that (1) the hepatic uptake of chemically different bile acids is compatible with carrier-mediated transport, (2) the maximal uptake velocity is higher for trihydroxy than for dihydroxy bile acids and is not influenced by conjugation, and (3) the affinity of bile acids for the transport system is higher for dihydroxy than for trihydroxy bile acids and higher for conjugated than for unconjugated bile acids.

2787 VARIATION IN BILE COMPOSITION AND SERUM LIPIDS DURING THE MENSTRUAL CYCLE. (Eng.)

Low-Beer, T. S.; Wicks, A. C. B.; Heaton, K. W.; Durrington, P.; Yeates, J. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 183-190; 1977.

To determine if there are fluctuations in bile cholesterol saturation and consequently in the risk of forming gallstones during the cycle, biliary lipid composition and fasting serum cholesterol and triglyceride levels were measured during the normal menstrual cycle in 11 healthy, regularly menstruating women not taking oral contraceptives. Measurements were made the day after bleeding had stopped, at midcycle, and 8-9 days after midcycle. Cholesterol saturation of bile, and therefore the risk of developing gallstones, was greater 8-9 days after midcycle than at the end of bleeding. Serum triglyceride and cholesterol levels fell over the 8-9 days after midcycle; triglyceride levels were 0.59 ± 0.07, 0.67 ± 0.06, and 0.52 ± 0.04 mM and cholesterol levels were 3.97 ± 0.01, 3.92 ± 0.16, and 3.63 ± 0.16 mM at the end of menstruation, at midcycle, and at 8-9 days after midcycle, resp. These changes in serum and biliary lipid composition are probably due to a direct effect of sex hormones on the liver.

2788 REAPPRAISAL OF CHOLESTEROL SOLUBILIZATION IN BILE SALT-LECITHIN SOLUTION AND THE STABILITY OF BILE. (Eng.) Furusawa, T.; Nakama, T.; Itoh, H.; Hisadome, T. (Faculty Medicine, Kyushu Univ., 3-1-1 Maidashi, Higashi-ku, Fukuoka-shi, 812 Japan). *Gastroenterol. Jpn.* 12(4):253-262; 1977.

Cholesterol solubility in aqueous solutions containing lecithin and bile salts in a 1:3 ratio by weight was studied. Both the rate and magnitude of cholesterol solubilization were found to be markedly greater in systems where a cholesterol and lecithin mixture was solubilized by the bile salt than in systems where cholesterol crystals were solubilized in an aqueous bile salt-lecithin solution. An almost linear relation was found between the quantity of solubilized cholesterol and the bile salt concentration when sodium deoxycholate was used as the bile salt; however, a slight deviation from a straight line was observed at lower bile salt concentrations (75 mM or less) when systems employing sodium cholate, sodium chenodeoxycholate, or sodium cholate-deoxycholate as bile salts were used. Thus, a partial straight line was drawn by the method of least squares, and the slope of the graph representing quantity of solubilized cholesterol as a function of bile salt concentration was calculated. The values of the slope for cholate, chenodeoxycholate, deoxycholate, and mixed equimolar cholate-deoxycholate systems were 5.85×10^{-2}, 7.60×10^{-2}, 9.50×10^{-2}, and 7.17×10^{-2}, resp. This order of values was the same as that obtained for bile salt-cholesterol systems without lecithin; however, the values obtained for the systems containing lecithin showed that the solubilizing power of the bile salt was intensified by the addition of lecithin in each system. The solubilized cholesterol:bile salt ratio was also graphed as a function of bile salt concentration, and the saturability of cholesterol solubilization in bile was illustrated when reported data on bile salts and cholesterol in human and animal bile were plotted on this graph.

2789 INTERACTION BETWEEN DRUGS AND CHOLESTEROL METABOLISM IN RAT LIVER SUBCELLULAR FRACTIONS. (Eng.) Mitropoulos, K. A.; Balasubramaniam, S. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 17-24; 1977.

The activities of cholesterol 7α-hydroxylase, ethylmorphine demethylase, and the microsomal concentration of cytochrome P-450 were compared in rat livers subsequent to the following *in vivo* treatments: phenobarbitone (100 mg/kg, i.p.) given on alternate days over 6 days; L-thyroxine (500 µg/kg, i.p.) given daily for 7 days; cholestyramine (5% in the diet) fed for 5 days; or thyroidectomy, portacaval anastomosis, or adrenalectomy performed 2 weeks before the experimental measurements. There was no correlation between the activity of cholesterol 7α-hydroxylase and that of ethylmorphine demethylase or the content of cytochrome P-450, but there was a close correlation between ethylmorphine demethylase activity and the concentration of cytochrome P-450. The presence of ethylmorphine inhibited the activity of cholesterol 7α-hydroxylase and the presence of cholesterol inhibited the activity of ethylmorphine demethylase. The activity of lanosterol 14α-demethylase was also inhibited in the presence of drugs such as ethylmorphine or aniline. Triarimol (α-[2,4-dichlorophenyl]-α-phenyl-5-pyrimidine-methanol), a drug that interacts with cytochrome P-450, was a potent inhibitor of cholesterol 7α-hydroxylase, lanosterol 14α-demethylase, and ethylmorphine demethylase activities. It is possible that liver microsomes contain a number of P-450s, each one specific for a given substrate.

2790 ROLE OF DIETARY CHOLESTEROL ON THE EFFECT OF CHENODEOXYCHOLIC ACID ON BILIARY LIPIDS. (Eng.) Coyne, M. J.; Bonorris, G. G.; Chung, A.; Cove, H.; Schoenfield, L. J. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, MD.: University Park Press): 203-209; 1977.

To determine the effects of differing concentrations of dietary cholesterol on the ability of chenodeoxycholic acid (CDC) to inhibit hepatic hydroxy-methyl-glutaryl-CoA reductase (HMG-CoAR) male golden Syrian hamsters were fed one of the following diets for 1 month: standard diet and CDC, high cholesterol diet with and without CDC, or cholesterol-free diet with and without CDC. The high cholesterol diet increased the concentration of biliary cholesterol and the biliary saturation index from the values observed in hamsters fed the standard diet but had no effect on bile acid or phospholipid concentrations. CDC administration significantly decreased the concentration of biliary cholesterol and the biliary saturation index from levels seen in hamsters on the standard diet and on the high cholesterol diet but had no effect on biliary acid or phospholipid concentrations. CDC had no effect on the concentration of biliary lipids or the biliary saturation index in the hamsters on the cholesterol-free diet. The hamsters receiving the high cholesterol diet and CDC had an HMG-CoAR activity less than that seen in hamsters receiving CDC and a standard diet. CDC administration to hamsters fed the cholesterol-free diet resulted in HMG-CoAR activity greater than the activity associated with CDC-treated hamsters on the standard diet. It is concluded that dietary cholesterol is necessary for optimum CDC inhibition of HMG-CoAR. Dietary cholesterol alterations may be one cause for the failure of CDC dissolution of gallstones because high cholesterol and cholesterol-free diets prevent the maximum CDC decrease of the biliary saturation index.

2791 CONVERSION OF 5β-CHOLESTANE INTERMEDIATES (3α,7α,26-TRIOL,3α,7α,25-TRIOL AND 3α,7α-DIOL) TO CHOLIC AND CHENODEOXYCHOLIC ACIDS IN MAN. (Eng.) Vlahcevic, Z. R.; Schwartz, C. C.; Cohen, B. I.; Gregory, D. H.; Halloran, L. G.; Kuramoto, T.; *et al. In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 49-58; 1977.

The efficiency of the conversion of the 5β-cholestane derivatives 3α,7α,26-triol,3α,7α-diol (both ^{3}H-labeled), and 3α,7α,25-triol (^{14}C-labeled) to cholic acid and chenodeoxycholic acid (CDCA) was examined by mixing the derivatives with albumin and giving the mixtures i.v. to postcholecystectomized patients who had balloon occludable T-tubes. The patients had acholic stools and no deoxycholic acid was found in bile, suggesting a completely interrupted enterohepatic cycle. The transformation of the injected labeled precursors was evaluated from the secretion rates of cholic acid and CDCA, the value of bile secreted per time period, and the specific activities of these respective bile acids. 5β-Cholestane-3α,7α,26-triol was efficiently converted to cholic acid and CDCA. The formation of cholic acid from this precursor suggests that hydroxylation at the 12 position is not hindered by the presence of a hydroxyl group at C-26. The efficient conversion of 5β-cholestane-3α,7α,26-triol and -3α,7α-diol into both cholic acid and CDCA in proportions similar to those observed for endogenously synthesized bile acids suggests that these 5β-cholestane derivatives may be major intermediates in the synthesis of cholic acid and CDCA. 5β-Cholestane-3α,7α,25-triol was poorly converted to bile acids, suggesting that this intermediate can be hydroxylated at the C-12 position to a limited extent. The quantitative contribution of this pathway to cholic acid synthesis is probably not very significant.

2792 TECHNIQUES FOR STUDYING LITHOCHOLIC ACID METABOLISM IN MAN. (Eng.) Allan, R. N.; van Berge-Henegouwen, G. P.; Hoffman, N. E.; Hofmann, A. F. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 161-165; 1977.

Factors involved in the development of techniques for accurate studies of lithocholic acid metabolism in man are considered. Simultaneous kinetic studies in gallstone patients and healthy volunteers indicated that (24-^{14}C)-lithocholate is a better label than (11,12-^{3}H)-lithocholate because it is more stable during enterohepatic cycling. Early bile acid pool sampling is essential for kinetic studies to avoid underestimating the specific activity at zero time and thus overestimating the pool size. Measurement of radioactivity in bile samples is done using standard methods. Preparative steps must include complete recovery of bile acid sulfates; complete hydrosolvolysis can be achieved by mild alkaline hydrolysis in nickel bombs using nordeoxycholic acid as an internal standard. Because of the complex kinetics involved, the most accurate estimates of the input and size of the total exchangeable lithocholate pool were obtained by using the Hamilton-Stewart equations. Lithocholate biotransformation studies are best done by i.v. administration of labeled bile acid with determination of the chemical form of radioactivity in bile samples by thin-layer chromatography. These techniques have been used to demonstrate that, during chenic acid ingestion, the lithocholate input and the size of the exchangeable pool in gallstone patients is four to five times that observed in healthy controls.

2793 THE METABOLISM OF URSODEOXYCHOLIC ACID IN MAN. (Eng.) Salen, G.; Fedorowski, T.; Colallilo, A.; Tint, G. S.; Mosbach, E. H. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 167-172; 1977.

The metabolism of ursodeoxycholic acid (UDCA) was investigated in man by feeding five subjects 1 g/day UDCA and another five subjects 1 g/day chenodeoxycholic acid (CDCA), all for 3 weeks. Biliary and fecal bile acid compositions were determined, biliary cholesterol saturation was measured, and the pool size and production rate of ursodeoxycholic acid was calculated after (24-^{14}C)-ursodeoxycholic acid was given i.v. as a pulse-label. Two weeks after administration, UDCA was the major biliary bile acid; the concentration of lithocholic acid was unchanged. When CDCA was given, 64% of the bile acids were CDCA and the concentration of lithocholic acid in the bile doubled. Following CDCA treatment, most of the fecal bile acids were present as their bacterial metabolites. Fewer bacterial derivatives were present in the feces when UDCA was given. This finding suggests that intestinal bacteria metabolize the 7β-hydroxy group of UDCA differently than the 7α-hydroxy group of CDCA. This difference in metabolism results in the formation of less lithocholic acid and fewer side-effects (stool frequency and serum transaminase levels) following UDCA treatment. During UDCA treatment, cholesterol saturation in the bile decreased significantly suggesting that UDCA, like CDCA, may be an effective litholytic agent.

2794 PRODUCTION OF COLLAGEN AND ACIDIC GLYCOSAMINOGLYCANS BY AN EPITHELIAL LIVER CELL CLONE IN CULTURE. (Eng.) Sakakibara, K.; Umeda, M.; Saito, S.; Nagase, S. (Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minatoku, Tokyo, 108, Japan). *Exp. Cell Res.* 110(1):159-165; 1977.

Experiments were carried out to determine whether a rat liver cell clone, which is known to produce collagen fibers *in vitro*, also produces glycosaminoglycans. The epithelial cell line produced collagen *in vitro* as early as 10 days after inoculation of the cells. The amount of collagen in the cell layers increased linearly with time after the cultures reached a saturation density. Two kinds of acidic glycosaminoglycans, hyaluronic acid and dermatan sulfate, were detected from the same cell layers by the combined method of electrophoresis and enzymic hydrolysis. Quantitative analysis by densitometry with an electrophorogram showed a rapid increase of both sulfated and nonsulfated glycosaminoglycans occurring concurrently with an accumulation of collagen. Histochemical stainings revealed that the majority of Alcian blue-positive materials was located outside the cells, where argyrophilic fibers could be found. These data are consistent with results obtained from biochemical experiments on cirrhotic rat livers, suggesting that liver parenchymal cells are responsible for an accelerated production of both collagen and glycosaminoglycans in liver cirrhosis.

2795 THE ROLE OF THE LIVER IN BIOSYNTHESIS OF THE NONVITAMIN K-DEPENDENT CLOTTING FACTORS. (Eng.) Workman, E. F., Jr.; Lundblad, R. L. (Dept. Pathology and Biochemistry, Univ. North Carolina, Chapel Hill, NC). *Semin. Thromb. Hemostas.* 4(1):15-28; 1977.

The role of the liver in the biosynthesis of the procoagulant proteins (factor V, VIII, XI, XII, and XIII, fibrinogen, prekallikrein, and high molecular weight kininogen), of proteins involved in fibrinolysis (plasminogen and plasminogen activator), and of the inhibitors, antithrombin III, α_2-macroglobulin, and α_1-antitrypsin is reviewed. The liver is the primary site of fibrinogen synthesis. There is evidence to support the role of fibrinogen degradation products in enhancing fibrinogen synthesis in some animal systems. Free fatty acid/albumin ratio may play a role in the increased fibrinogen synthesis observed during disseminated intravascular coagulation. Factor VIII appears to be synthesized primarily in the liver endothelial cells. Factor XIII activity (a-chain) may be synthesized at a variety of sites (megakaryocytes, spleen, uterus), while b-chain synthesis is probably confined to the liver. Factor V also appears to be synthesized by the liver, as evidenced by the decrease of its plasma concentration in patients with liver damage and its presence in perfusates from isolated rat liver. It is likely that the synthesis of factors XIII and XI, prekallikrein, and high molecular weight kininogen occur in the liver, but no direct evidence is available. Plasma antithrombin III levels decreased in all studied cases of severe hepatic failure both with and without evidence of disseminated intravascular coagulation, suggesting that the liver participates in antithrombin III synthesis. Embryonic hepatic tissue synthesizes α_2-macroglobulin, but the plasma level of this inhibitor is elevated in patients with severe liver disease, suggesting the existence of extrahepatic sites of synthesis. α_1-Antitrypsin also appears to be synthesized at least in part by the liver.

2796 EFFECT OF ESTROGEN ON LIVER DAMAGE. (Eng.) Inokawa, H. (Nihon Univ. Sch. Medicine, Nihon, Japan). *Nihon Univ. J. Med.* 18(2):75-89; 1976.

The effects of estrogen and ACTH fatty degeneration and fibrosis of the liver were studied in female rats receiving a choline-deficient diet. Both castrated and noncastrated rats were injected (3 times/week, i.p.) with estrogen (0.02% or 0.2% solution given in doses of 0.05 ml or 0.1 ml per 100 g body weight) or ACTH (IU/10 ml solution, dose of 0.05 ml/100 g body weight). The animals were sacrificed 1 or 2 months after the start of the study. The estrogen had a mild protective effect against fatty liver, which is induced by a choline deficient diet but it appeared to induce liver fibrosis. ACTH, however, protected against liver fibrosis in noncastrated rats but increased the development of fatty liver in rats on the choline-deficient diet. Estrogen suppressed the production of serum mucoprotein.

2797 REVERSAL OF ETHINYL ESTRADIOL-INDUCED HYPOCHOLESTEROLEMIA AND CHOLESTASIS BY TRITON WR-1339. (Eng.) Davis, R. A.; Showalter, R. B.; Kern, F., Jr. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October 1976.* (Baltimore, MD: University Park Press): 25-31; 1977.

To examine hepatic lipid composition in relation to estrogen-impaired liver function, male Sprague-Dawley rats were injected s.c. daily with ethinyl estradiol (5 mg/kg/day) for 5 days to produce maximal hypocholesterolemia, after which they were injected with Triton WR-1339 (22.5 mg/100 g). Some rats were killed 15 hr after Triton WR-1339 injection for determination of hepatic cholesterol concentration and microsomal cholesterol acyl-CoA transferase; other rats were used for bile flow measurements. Ethinyl estradiol caused hepatic cholesterol concentrations to double but had no effect on free cholesterol levels. Triton WR-1339 reduced the concentration of hepatic cholesterol esters to normal levels. Addition of Triton WR-1339 to hepatic microsomal fractions from ethinyl estradiol-treated rats inhibited cholesterol esterification in a log-linear dose relationship, suggesting that Triton lowers hepatic cholesterol ester concentrations by inhibiting the activity of this enzyme. The rate of bile flow, which was reduced by 50% in ethinyl estradiol-treated rats, was restored to control values by Triton. It is concluded that Triton WR-1339 reverses estrogen-induced hepatic cholesterol ester accumulation and also reverses two impaired hepatic functions: hypocholesterolemia and decreased bile salt independent bile flow. The data support the concept that, in part, estrogens alter hepatic function through the pleiotropic effects secondary to increased microsomal cholesterol acyl-CoA transferase activity.

2798 THE EFFECT OF SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN ON THE SECRETION OF BILE IN

THE ANAESTHETIZED RABBIT. (Eng.) Esteller, A.; Lopez, M. A.; Murillo, A. (Dept. Animal Physiology, Univ. Granada, Granada, Spain). *Q. J. Exp. Physiol.* 62(4):353-359; 1977.

The effects of secretin and cholecystokinin-pancreozymin (CCK-PZ) on the secretion of bile in anesthetized rabbits were studied. Single injections of secretin (5.0 U/kg, i.v.) significantly increased the flow of bile irrespective of whether the cystic duct was free or had been tied. A sustained increase in bile flow was obtained by the continuous infusion of secretin. CCK-PZ was effective in increasing the bile flow in doses of 1.0 U/kg. Much of the effect could be attributed to contraction of the gallbladder, but a significant increase in flow could still be elicited after ligation of the cystic duct. These findings strongly suggest that the biliary secretion in rabbits is not as different from the general pattern as has previously been suggested.

2799 CYSTIC CHOLANGIOFIBROSIS OF THE LIVER. (Eng.) Dominis, M.; Damjanov, I. (Bolnica O. Novosel, Zajeeva ul. 19, Zagreb, 41000 Yugoslavia). *Arch. Geschwulstforsch.* 47(7):661-669; 1977.

Hepatic cysts in rats fed acetylaminofluorene were studied ultrastructurally to further characterize the lesion and its histogenesis. The cysts were lined by cuboidal or flattened epithelium or both and resembled bile ductular cells. Most of the flattened cells showed adaptive and degenerative changes indicative of pressure atrophy. The cuboidal cells lining the smaller ducts showed ultrastructural signs of activity. Similar "active" cells were seen in the outpouchings of the larger cysts. These data indicate that the cysts are of cholangiocellular origin. Ultrastructurally, the cells forming the cysts showed no signs of anaplasia and more likely represent the end point of bile ductular proliferation rather than a stage in the development of biliary neoplasia.

2800 ULTRASTRUCTURAL ASPECTS OF BILIRUBIN ENCEPHALOPATHY IN COCHLEAR NUCLEI OF THE GUNN RAT. (Eng.) Jew, J. Y.; Williams, T. H. (Dept. Anatomy, Univ. Iowa, Iowa City, IA 52240). *J. Anat.* 124(3):599-614; 1977.

Ultrastructural changes occurring in the cochlear nuclei of Gunn rats with bilirubin encephalopathy were studied. Twenty-one homozygous Gunn rats (2 days to 7 months old) with conspicuous jaundice and/or symptoms of central nervous system disease were compared with normal Sprague-Dawley rats and heterozygous Gunn rats of appropriate age. Blocks containing the ventral cochlear nuclei and the dorsal cochlear nucleus were removed from the fixed brain and processed for electron microscopy by staining with uranyl acetate and lead citrate. Ultrastructural abnormalities were observed in all age groups of homozygous rats, being least severe in the 2- to 4-day old animals. Mitochondrial alterations were observed in 2-day-old rats. The amount of alpha and beta glycogen particles in mitochondria of large neurons increased with age. Some large ex-mitochondrial sacs in close proximity to glycogen filled vacuoles were observed. Dilated profiles of rough endothelial reticulum also contained glycogen particles. Elaborated myelin figures surrounded tongues of cytoplasm and vacuoles and degenerative elements were observed in the cytoplasm of some large neurons. It seems very likely that, in bilirubin encephalopathy, bilirubin affects primarily membrane functions, especially in the mitochondria.

2801 THE EFFECT OF D-GALACTOSAMINE ON LCAT SECRETION AND ULTRASTRUCTURE OF ISOLATED RAT HEPATOCYTES. (Eng.) Nordby, G.; Schreiner, B.; Berg, T.; Norum, K. R. (Sch. Medicine, Univ. Oslo, Blindern, Oslo, Norway). *Acta Pathol. Microbiol. Scand.* [*A*] 85(6):839-849; 1977.

The effect of D-galactosamine on the morphology and secretory activity of isolated rat hepatocytes was studied. Hepatocytes prepared from male Wistar rats were cultured *in vitro*. Cell viability was assayed and protein secretion estimated by measuring radioactivity in a precipitate derived from cultures incubated with [$U^{14}C$]protein hydrolysate. The activity of the secreted lecithin:cholesterol acyltransferase (LCAT) was determined. Total and unesterified cholesterol were estimated by gas liquid chromatography. The glycerol and the triacylglycerol were measured fluorimetrically. The secretion of LCAT from isolated hepatocytes was almost completely blocked when 5 mg/ml of galactosamine was added to the culture. The effect was measurable after 30 min of incubation but it was higher after 3-5 hr. After 3 hr of incubation with galactosamine, there was a slightly lowered secretion of both free cholesterol and triacylglycerol. Galactosamine inhibited the secretion of labeled proteins from the hepatocytes. Viability of the cells was unaffected by the addition of galactosamine. A striking feature of galactosamine-treated hepatocytes was the appearance of dilated lysosomes that were formed by the selective uptake of galactosamine or its metabolites. A large amount of glycogen was observed in cells incubated with both uridine and galactosamine. Galactosamine-treated rat hepatocytes may be a useful model for the study of the interrelationships between LCAT and lipoprotein secretion.

SECRETION AND METABOLISM

Intestine

2863 ROLE OF GASTROINTESTINAL HORMONES IN THE RESPONSE TO MASSIVE RESECTION OF THE SMALL BOWEL. (Eng.) Barros D'Sa, A. A. B.; Buchanan, K. D. (Queen's Univ. Belfast, Inst. Clinical Science, Grosvenor Rd., Belfast BT12 6BJ, Northern Ireland). *Gut* 18(11):877-881; 1977.

The effects of a 75% resection of the distal small bowel on the circulating levels of a range of gastrointestinal hormones were investigated in dogs to define the role of these hormones in the hypersecretion of gastric acid and the accelerated intestinal transit observed after massive enterectomy. Basal and meal-stimulated concentrations of insulin, secretin, gastrin, pancreatic glucagon, and total glucagon-like immunoreactivity (GLI) were measured by radioimmunoassay techniques. After resection, significant depletions of basal and stimulated total GLI ($p<0.05$, $p<0.001$) and a significant rise of stimulated gastrin ($p<0.05$) were discovered. These hormonal alterations may produce an important imbalance of humoral influences on gastrointestinal function. It is suggested that these changes may hold a key to the etiology of the complications of massive resection of the small bowel.

2864 PROXIMAL ENTERECTOMY STIMULATES DISTAL HYPERPLASIA MORE THAN BYPASS OR PANCREATICOBILIARY DIVERSION. (Eng.) Williamson, R. C. N.; Bauer, F. L. R.; Ross, J. S.; Malt, R. A. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 74(1):16-23; 1978.

To help differentiate among the factors responsible for postresectional intestinal hyperplasia, cell proliferation in the distal intestine of male Sprague-Dawley rats was studied after 50% proximal enterectomy or 50% proximal bypass and also after transposition of the duodenal papilla to the mid small bowel. Within 48 hr, all three operations increased RNA and DNA contents in the ileal mucosa 16% to 50% over control values. At 48 hr and 1 week, the response distal to resection exceeded that of bypass or pancreaticobiliary diversion; nucleic acid contents, DNA specific activity, villous height, crypt depth, and luminal circumference were greatest 1 week after resection. By 1 month, however, chemical and histological values after resection were equalled or surpassed by those in the other two groups. In excluded jejunum itself, mucosal atrophy lowered RNA and DNA contents to 60% of control levels 1 month postoperatively. Neither pancreaticobiliary diversion nor proximal enteric bypass produces the same rate of distal hyperplasia as proximal resection. Modest colonic hyperplasia may contribute to intestinal adaptation after proximal enterectomy. Adaptive postresectional cell proliferation appears not to be mediated by intraluminal nutrition or enteric secretions alone; hormonal factors may also be important.

2865 EXPERIMENTAL SHORT GUT: HEPATIC ALTERATIONS AFTER JEJUNOILEAL RESECTION, BYPASS AND VIBRAMYCIN THERAPY. (Eng.) Burney, D. P.; Burnham, S. J.; Hough, A. J.; Scott, H. W. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *Am. Surg.* 43(12):778-786; 1977.

The hypothesis that *Bacteroides* endotoxin absorbed from the bypassed segment in the end-to-side jejunoileal bypass is the causative factor in postintestinal bypass hepatic failure was tested in 18 dogs with and without concomitant administration of an oral broad spectrum antibiotic (Vibramycin, 100 mg/day). The study was done in two phases on two groups of dogs. In phase 1, six dogs underwent a greater than 80% jejunoileal resection and end-to-end anastomosis of 24 inches of proximal jejunum to 12 inches of distal ileum. Twelve dogs had no resection but the same degree of bypass. The ileal end of the bypassed segment was anastomosed to the side of the mid-transverse colon; the proximal end of the bypassed small bowel was closed and sutured to the mesentery. Six of the latter 12 dogs received the antibiotic. All dogs had progressive weight loss followed by stabilization and normal liver function test, hemograms, and liver biopsies during the 6-month observation period. In the 12 bypass-operated dogs, bacterial cultures for aerobes and anaerobes showed identical flora, irrespective of antibiotic therapy. The bowel was then shortened further in all dogs (phase 2) to leave only 16 inches of small gut (10 inches of duodenum and proximal jejunum plus 6 inches of distal ileum) from pylorus to cecum. Antibiotic therapy was continued as before for six dogs. Dogs subjected to resection in phase 1 showed essentially normal chemical tests (serum hemoglobin, WBC counts, total protein concentration, serum albumin level, LDH, SGOT, alkaline phosphatase levels, and bilirubin) and liver biopsy results following phase-2 operation; there was one anesthetic death at the second operation and one death from malnutrition 6 months after the reshortening. Chemical and histologic (e.g., hepatic steatosis and cellular necrosis) evidence of hepatic failure developed in all 12 bypass-operated dogs, both with and without antibiotic therapy. Multiple aerobic and anaerobic bacteria were demonstrated in all dogs. Three resected dogs and three bypass-operated dogs each yielded one *Bacteroides* species. No bacterial overgrowth occurred. The results suggest that hepatic disease occurs consistently with severely shortened gut plus jejunoileal bypass, but not with severely shortened gut and jejunoileal resection. These data do not support the theory that hepatic failure results from overgrowth of a specific bacterial strain since antibiotic treatment did not prevent hepatic cellular necrosis or qualitatively alter the bacterial flora cultured from the bypassed segment.

2866 INTESTINAL CALCIUM-BINDING PROTEIN 3 MONTHS AFTER MASSIVE SMALL BOWEL RESECTION IN THE PIGLET. (Eng.) Margolis, A.; Ricour, C.; Harouchi, A.; Guyot, M.; Laouari, D.; Balsan, S. (Hopital des Enfants Malades, 75730 Paris, Cedex 15, France). *Am. J. Clin. Nutr.* 30(2):2041-2046; 1977.

The adaptive changes in intestinal calcium-binding protein and calcium binding activity were studied at resection and 3 months after 90% small bowel resection in piglets and one adult pig. A calcium-binding protein (molecular weight$\approx$11,000) with calcium-dependent electrophoretic mobility was partially purified from mucosal extract of proximal jejunum, mid-gut, and ileum. The concentration of calcium-binding protein and the calcium-binding activity of the intact animals were highest in the proximal jejunal segment and lowest in the ileal segment. After resection in the four surviving animals out of nine, a significant increase in calcium-binding activity was observed in the proximal jejunum and in the distal ileal segment. The change in calcium-binding activity was much more marked in the ileum than the jejunum. These data demonstrate that pig intestinal mucosa possesses an adaptive capacity to increase the synthesis of calcium-binding protein after massive small bowel resection.

2867 MECHANISM OF PRODUCTION OF INTESTINAL SECRETION BY NEGATIVE LUMINAL PRESSURE. (Eng.) Hakim, A. A.; Papeleux, C. B.; Lane, J. B.; Lifson, N.; Yablonski, M. E. (Univ. Minnesota Medical Sch., Minneapolis, MN 55455). *Am. J. Physiol.* 233(5):E416-E421; 1977.

The relationships between luminal hydrostatic pressure and fluid transport by dog jejunum *in vivo* were compared with quantitative predictions from a model proposed for the mechanism of the secretion produced by elevated venous pressure. Hydrostatic pressure and fluid transport were studied in sheets of jejunum inserted in a Wells clamp. According to the model, the secretion produced by increasing venous pressure and the secretion produced by negative luminal pressure are both passive filtrates contingent on a transepithelial pressure of a few centimeters of H_2O. The agreement between the observed and predicted responses to luminal pressure provided strong support for the model. In particular (a) the observations displayed a predicted gross asymmetry in rates of fluid transfer with isotonic fluids, depending on whether the luminal pressure was positive or negative; (b) the observed magnitude of the negative luminal pressure required for the onset of secretion agreed with predictions; and (c) the secretion contained significant amounts of protein at about 25% of the plasma concentration.

2868 LAMINA PROPRIA MACROPHAGES OF INTESTINE OF THE GUINEA PIG: POSSIBLE ROLE IN PHAGOCYTOSIS OF MIGRATING CELLS. (Eng.) Sawicki, W.; Kucharczyk, K.; Szymanska, K.; Kujawa, M. (Sch. Medicine, Chalubinskiego 5, 02-004 Warsaw, Poland). *Gastroenterology* 73(6):1340-1344; 1977.

To test the hypothesis that lamina propria macrophages may play a role in phagocytosis of nuclear material originating from migrating cells of the intestinal mucosa, these macrophages were studied in the guinea pig, mouse, and rat small and large intestines, and in human duodenum. The macrophages of lamina propria were commonly found both in the small and the large intestine of all these species. The frequency of macrophage occurrence was highest in the lamina propria of villus apices of the small intestine and beneath the lining epithelium of the large intestine. In the cytoplasm of lamina propria macrophages localized in those regions, Feulgen-positive (DNA-containing) granules were observed, particularly in the guinea pig intestine. Autoradiography of the latter, 3 to 5 days after $[^3H]$thymidine injection, showed the coincidence of occurrence of labeled Feulgen-positive granules in the macrophage cytoplasm with the appearance of labeled epithelial cells and sheath-fibroblasts in the region of lamina propria containing the highest accumulation of macrophages, i.e., at the apices of villi of the small intestine and beneath the lining epithelium of the large intestine. Labeled nuclei of macrophages were observed much less frequently than were labeled cytoplasmic granules. No labeled Feulgen-positive granules were seen in macrophages 0.5 hr, 1, 2, or 7 days after [^{3}H]thymidine injection. The lamina propria macrophages may play a role in the phagocytosis of some migrating cells of the intestinal mucosa, most probably of the sheath fibroblasts and/or intra-epithelial lymphocytes.

2869 EFFECTS OF TETRACYCLINE HYDROCHLORIDE ON ALBINO RAT INTESTINAL MUCOSA. (Eng.) Sehgal, A. K.; Chhuttani, P. N.; Habibullah, C. M. (Postgraduate Inst. Medical Education and Res., Chandigarh, India). *J. Indian Med. Assoc.* 68(4): 69-71; 1977.

The effect of tetracycline on rat intestinal mucosa was investigated. Two groups of animals received tetracycline (6 mg/100 g/day) p.o. for 15 days or 2 months, resp., while a control group received placebo. There was an increase in the height of the villi and an increase in the depth of the crypts in the duodenal and jejunal mucosa in both the short-term and long-term drug groups. This effect was reversible. There were few differences in the changes observed in the short-term and long-term groups. There was no change in the epithelial cell height. The cell count in the corium decreased in three regions in the treated animals.

2870 SALVAGE OF ADENOSINE, INOSINE, HYPOXANTHINE, AND ADENINE BY THE ISOLATED EPITHELIUM OF GUINEA PIG JEJUNUM. (Eng.) Kolassa, N.; Stengg, R.; Turnheim, K. (Pharmakologisches Institut, Universitat Wien, Wahringerstr., 13a, A-1090 Vienna, Austria). *Can. J. Physiol. Pharmacol.* 55 (5):1039-1044; 1977.

The metabolism of ^{14}C-labeled adenosine, inosine, hypoxanthine, and adenine (all at 5×10^{-6} M) was studied in isolated epithelium of guinea pig jejunum. When adenosine or adenine was added to the antiluminal side of the epithelium, two-thirds or one-half, resp., of cellular radioactivity was incorporated into the nucleotide fraction, mainly in the form of adenine nucleotides. Nucleotide synthesis from inosine or hypoxanthine was significantly smaller than that from adenosine. By contrast, another metabolic pattern was found after luminal administration of adenosine, inosine, or hypoxanthine; the incorporation rate into the nucleotide fraction was equally high, and the label was recovered in inosine monophosphate (IMP) and adenine nucleotides to about the same extent with all three substrates. Purine riboside (10^{-4} M) significantly depressed nucleotide formation from adenosine, with respect to IMP formation in particular, while no change was observed in inosine or hypoxanthine salvage. The results suggest compartmentation of the enzymes of purine metabolism within the intestinal mucosa.

2871 PROPRANOLOL INHIBITS BILE ACID AND FATTY ACID STIMULATION OF CYCLIC AMP IN HUMAN COLON. (Eng.) Coyne, M. J.; Bonorris, G. G.; Chung, A.; Conley, D.; Schoenfield, L. J. (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *Gastroenterology* 73(5):971-974; 1977.

The effect of bile acids, fatty acids, catecholamines, and propranolol on cyclic AMP (cAMP) was studied in human colonic mucosa to study the role of cAMP in bile acid- and fatty acid-induced diarrhea. In normal colonic mucosa obtained at surgery, the effects on cAMP synthesis of 10^{-5} M deoxycholic acid, 10^{-5} M cholic acid, 10^{-5} M 9,10-hydroxystearic acid, 10^{-5} M oleic acid, 10^{-4} M epinephrine, and 10^{-4} M norepinephrine were studied in six experiments. In tissue incubated with 10^{-5} M deoxycholic acid or 9,10-hydroxystearic acid, the effect on cAMP of 10^{-6} M propranolol, with and without 10^{-4} M epinephrine, or 10^{-4} M norepinephrine was studied in six more experiments. Deoxycholic acid increased adenylate cyclase (AC) activity 203% ($p<0.01$), and 9,10-hydroxystearic acid increased AC 236% ($p<0.01$). No other agents stimulated AC. Propranolol decreased basal AC 43% ($p<0.01$), deoxycholic acid stimulated AC 46% ($p<0.01$), and hydrostearic acid stimulated AC 37% ($p<0.01$). Epinephrine or norepinephrine did not reverse these decreases. None of the agents affected phosphodiesterase. Deoxycholic acid and 9,10-hydroxystearic acid stimulate AC in human colonic mucosa, suggesting that bile acid- and fatty acid-induced diarrhea are mediated by the cAMP system. Because propranolol prevents this AC stimulation, propranolol should be investigated as a possible treatment for these diarrheal conditions.

2872 LACK OF CIRCADIAN RHYTHMICITY OF RAT FETAL INTESTINAL ENZYMES AS COMPARED TO THE DAMS. (Eng.) Stevenson, N. R.; Byra, W. M.; Day, S. E. (Rutgers Medical Sch., Piscataway, NJ 08854). *Dev. Biol.* 60(2):487-492; 1977.

To study endogenous rhythms of intestinal enzymes and the need for p.o. and/or intermittent intake for the maintenance of these rhythms, the 24-hr activity patterns of intestinal maltase, lactase, leucylnaphthylamine hydrolyzing activity, γ-glutamyltransferase, and alkaline phosphatase were determined in pregnant rats maintained on a 12-12 light-dark cycle, with feeding during the dark period (1800-0600 hr). The activities of these enzymes plus those of lysosomal maltase and lactase were followed during the same time period in 19- to 20-day-old fetuses. The activity patterns in the dams followed circadian rhythms, with peak activities occurring during the feeding-dark period. These rhythms were similar to the feeding schedule-cued rhythms observed in male rats and, therefore, are assumed to be feeding schedule cued also. In the fetuses, the activities increased in a nonlinear manner throughout the entire 24-hr period, but did not display a defined rhythm. It is concluded that endogenous intestinal enzyme rhythms do not exist *in utero*, and that p.o. and/or intermittent feeding is necessary for these rhythms to occur.

2873 STIMULATION OF ADENYLATE CYCLASE IN HOMOGENATES OF ISOLATED INTESTINAL EPITHELIAL CELLS FROM HAMSTERS: EFFECTS OF GASTROINTESTINAL HORMONES, PROSTAGLANDINS, AND DEOXYCHOLIC AND RICINOLEIC ACIDS. (Eng.) Gaginella, T. S.; Phillips, S. F.; Dozois, R. R.; Go, V. L. W. (Coll. Pharmacy, Ohio State Univ., Columbus, OH 43210). *Gastroenterology* 74(1):11-15; 1978.

The ability of gastrointestinal hormones to stimulate intestinal adenylate cyclase was studied in isolated small intestinal villus cells of the hamster, because the mechanism by which intestinal secretagogues evoke fluid secretion in the small bowel and colon has been suggested to involve mucosal adenylate cyclase. Adenylate cyclase activity was assayed by conversion of $[^{32}P]$ATP to $[^{32}P]$cyclic AMP in a system of pure epithelial cells isolated by vibration in buffer. Vasoactive intestinal peptide and impure cholecystokinin-pancreozymin (but not the 99% pure preparation or pure cholecystokinin octapeptide) were potent stimuli of adenylate cyclase, but pentagastrin, glucagon, secretin, and gastric inhibitory peptide were impotent. Prostaglandins E_1 and E_2 were potent stimuli of adenylate cyclase. Deoxycholic acid and ricinoleic acid were ineffective stimuli of adenylate cyclase. These experiments do not support a clear-cut relation between a compound's ability to stimulate adenylate cyclase and its activity as an intestinal secretagogue.

2874 STIMULATION OF INTESTINAL Ca^{2+}-ATPase ACTIVITY BY CYSTEINE. (Eng.) Matsuda, T.; Maeda, S.; Baba, A.; Iwata, H. (Dept. Pharmacology, Osaka Univ., 133-1, Yamada-kami, Suita-shi, Osaka, Japan). *Life Sci.* 21(7):915-920; 1977.

Small intestinal calcium transport was studied *in vitro* in male Sprague-Dawley rats. Cysteine (0.1 mM) stimulated the activity of the ATPase dependent on Ca^{2+}, but not those dependent on Mg^{2+} and Zn^{2+}, in the microsomal and brush border fractions of the duodenal mucosa. This Ca^{2+}-dependent ATPase was localized in the duodenum but was not present in the jejunum or ileum. Kinetic studies showed that cysteine did not change the K_m value for ATP but decreased that for Ca^{2+}. Glutathione, 2-mercaptoethanol, and dithiothreitol also stimulated the Ca^{2+}-ATPase activity. These findings suggest that thiol-containing reagents stimulate the Ca^{2+}-ATPase activity in the duodenum by affecting the interaction of the enzyme with Ca^{2+}.

2875 GLYCEROL-ESTER HYDROLASE FROM HUMAN SMALL INTESTINE AND ITS POSSIBLE ROLE IN THE DEGRADATION OF NEUTRAL LIPIDS. (Eng.) Negrel, R.; Serrero, G.; Ailhaud, G.; Rey, J. F.; Delmont, J. (Hopital de Cimiez, Nice, France). *Digestion* 16(1/2):146-159; 1977.

A glycerol-ester hydrolase (GEH, molecular weight of 70,000) was isolated from homogenized, scraped, human jejunal mucosa and identified by polyacrylamide-gel electrophoresis and specific staining, and partially characterized. The enzyme activity was essentially the same along the whole length of the intestinal wall as measured by hydrolytic activity against three substrates (tributyrin, *p*-nitrophenylacetate, and palmityl CoA), using tissues from intestinal biopsies or intestinal fragments. No cross-reaction was observed between GEH and immunoserum against human pancreatic juice, indicating the low contamination by pancreatic enzymes and supporting the intestinal origin of GEH. The optimum pH for GEH activity was 8.0 to 8.5, which excluded the possibility of contamination by acidic lipases of gastric or pharyngeal origin. The presence of neutral detergent increases the stability of activity against tributyrin and *p*-nitrophenylacetate; the coaxial peaks of activity against these substrates suggest that there is a single enzyme involved, the ratio being 3-4.2 along the peak. The thiolester hydrolase activity (against palmityl Co-A) was separated from that of GEH. The ratio of activity against tributyrin versus 1(3)-mono-olein remained constant along the purification, suggesting that hydrolytic activity against long-chain monoglycerides in human intestinal homogenates is caused by the glycerol-ester hydrolase. The enzyme was not completely inhibited by a mixture of bile salts mimicking human bile, so that it should remain at least partially active in the lumen where bile salts are present. There seems to be no significant variation in GEH activity in the jejuna of patients with pancreatic lipase deficiencies due to limited supplies of pancreatic juice; hence, GEH does not seem to respond to environmental factors. Substrates may be soluble (*p*-nitrophenylacetate), micellar (mono-olein), or emulsified (dioctanoin and trihexanoin) in form. Enzyme activity occurs preferentially on short-chain triglycerides and medium-chain diglycerides. Since patients presenting with lipid malabsorption disorders absorb medium-chain triglycerides efficiently, it is likely that there is partial hydrolysis by pharyngeal and pancreatic lipases. The partial glycerides can then be hydrolyzed by the glycerol-ester hydrolase in the lumen or intracellularly. Hence, GEH is postulated to play a role in the absorption of neutral lipids, particularly in pathological situations.

2876 3-HYDROXY-3-METHYLGLUTARYL COENZYME A REDUCTASE IN ISOLATED VILLOUS AND CRYPT CELLS OF THE RAT ILEUM. (Eng.) Merchant, J. L.; Heller, R. A. (Sch. Medicine, Stanford Univ., Stanford, CA 94305). *J. Lipid Res.* 18(6):722-733; 1977.

The localization of 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMG-CoA reductase) in the rat small intestinal villus and crypt cells was accomplished after separating these cells from the mucosal layer by sequential dissociation in a "dual-buffer" system. Consistent separation was demonstrated by using the marker enzymes alkaline phosphatase (specific to the villus cell) and thymidine kinase (specific to the crypt cell). Cells obtained were 95-100% viable, and no relative difference in lability was observed, as evidenced by the equal distribution of acid phosphatase. This method of cell separation was an improvement over the "scraping" technique that damaged cells severely and produced villus preparations that contained little or no reductase activity. The HMG-CoA reductase specific activity in whole cell homogenates of the ileal villi was 0.47 and of the crypts was 0.27 nmol/min/mg of protein, considerably higher values than have been reported earlier. Also, in comparison to the crypts, the villi incorporated 1.5-fold more [^{14}C]-acetate into sterols, a ratio similar to that describing the distribution of HMG-CoA reductase in the two cell populations. These results unequivocally establish that the villi have higher HMG-CoA reductase activity than do the crypts and confirm an earlier report from this laboratory that the villi are a major site of sterol synthesis. The sterol biosynthetic capacity of the small intestine was highest in the ileum and decreased towards the jejunum. The HMG-CoA reductase specific activity of the ileum averaged 0.30 and that of the jejunum 0.10 nmol/min/mg of protein; however, the cholesterol content of the ileum was slightly lower than the jejunum. These results suggest the possibility that the sterol content of the ileum may largely be due to *in situ* synthesis.

2877 DEVELOPMENT OF INTESTINAL BRUSH BORDER MEMBRANE PROTEINS IN THE RAT. (Eng.)

Seetharam, B.; Yeh, K. Y.; Moog, F.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Biochim. Biophys. Acta* 470(3):424-436; 1977.

The proteins of the intestinal microvillus membrane were studied during postnatal development in the rat (days 12-37). In suckling animals ($\leq$20 days), the majority of alkaline phosphatase, glucoamylase, and lactase activities in the distal half of the intestine were located in the supernatant fraction (100,000 x *g*, 60 min). These enzymes were attached to the membrane from the proximal intestine at all ages. Alkaline phosphatase, maltase, and lactase activities in the supernatant fractions chromatographed in Sephadex G-200 in positions similar to the corresponding membrane enzyme. Corresponding activities for lysosomal counterparts of maltase and lactase present in the supernatant fraction chromatographed differently. The pH optimum of the soluble enzymes was 9.2 for phosphatase and 5.5-6.0 for glycoamylase and lactase. The soluble lactase and alkaline phosphatase were inhibited minimally by *p*-chloromercuribenzoate and sodium fluoride, resp. L-phenylalanine (20 mM) inhibited the soluble phosphatase by 90%. Thus, the soluble enzymes are not mainly of lysosomal origin, but have characteristics of membrane-bound enzymes. Polyacrylamide gel electrophoresis in sodium dodecyl sulfate revealed 18 protein bands that were present in adult membranes. Two other proteins were unique for membranes of distal intestine in suckling rats. The proteins corresponding to known enzyme activity changed as expected with age (e.g., sucrase and maltase activities increased, lactase activity decreased). Most of the other proteins were also altered quantitatively during development. Thus, the changes in the microvillus membrane during development in the rat are not limited to specific enzymes.

2878 INTESTINAL 1,25-DIHYDROXYVITAMIN D$_3$ BINDING PROTEIN: SPECIFICITY OF BINDING. (Eng.)

Eisman, J. A.; DeLuca, H. F. (Coll. Agricultural and Life Sciences, Univ. Wisconsin-Madison, Madison, WI 53706). *Steroids* 30(2):245-257; 1977.

The binding of metabolites of vitamin D and their analogs to the 3.7S chick intestinal cytosol receptor protein was specifically studied by competitive binding techniques and polyethylene glycol precipitation of the complex. The structural requirements for the interaction between the vitamin D molecule and the receptor were assessed without the nuclear chromatin binding step. 1,25-Dihydroxyvitamin D$_3$ and 1,25-dihydroxyvitamin D$_2$ were found to be equally competitive and were the most active. Of the structural features of the compounds, the 1α-hydroxyl was found to be the most important followed by the 25-hydroxyl and the 3β-hydroxyl. The addition of a second hydroxyl near carbon 25 markedly reduced binding, whether on the 26 carbon or the 24 carbon. A hydroxyl on C-24 could substitute to some degree for the 25-hydroxyl, inasmuch as 24-hydroxyvitamin D$_3$ was much more effective than vitamin D$_3$ but less effective than 25-hydroxyvitamin D$_3$. In general, the patterns of binding affinities correlated well with the biological activity of the various analogs, which strongly supports a physiological role for the 1,25-dihydroxyvitamin D$_3$ binding protein. The results also suggest that, in the two-step receptor mechanism, the structural specificity is located in the initial interaction of the 1,25-dihydroxyvitamin D$_3$ and the cytosol receptor.

2879 CHANGES IN BLOOD SEROTONIN IN EXPERIMENTAL INTESTINAL OBSTRUCTION IN DOGS. (Eng.)

Ojha, S. C.; Sarkar, F. H.; Khanna, N. N.; Udupa, K. N. (Inst. Medical Sciences, Banaras Hindu Univ., Varanasi 221 005, India). *Indian J. Exp. Biol.* 15(10):931-932; 1977.

Changes in blood serotonin level were examined in dogs with experimental, acute simple, or strangulation obstructions of the proximal jejunum. A statistically significant increase ($p<0.01$) in the serotonin concentration was observed on the third day after acute simple obstruction was produced. In strangulation obstructions, a significant rise was seen 6 and 12 hr after operation ($p<0.01$ and $p<0.025$, resp.) in untreated animals, whereas no significant rise was seen in antibiotic-treated animals. Changes in blood serotonin levels appear to be important in toxemia complicating intestinal obstruction.

GENERAL

2893 THE INFLUENCE OF GASTRIC SURGERY ON THE INTESTINAL FLORA. (Eng.) Greenlee, H. B.; Gelbart, S. M.; DeOrio, A. J.; Francescatti, D. S.; Paez, J.; Reinhardt, G. F. (Veterans Admin. Hosp., Hines, IL). *Am. J. Clin. Nutr.* 30(11):1826-1833; 1977.

Varying degrees of vagal denervation and gastric resection were performed in dogs analogous to five different peptic ulcer operations commonly performed in patients, to study changes in bacterial flora. Postoperative cultures of the stomach and small bowel were obtained via laparotomy at intervals up to 1 yr. Quantitative aerobic and anaerobic bacteriological studies demonstrated a persistent and marked increase in the number of microorganisms comprising the flora of the upper small bowel after each of these gastric operations except parietal cell (proximal gastric) vagotomy. In parietal cell vagotomy, antral-duodenal parasympathetic innervation is preserved, and generally no modification of the gastric outlet is necessary unless stenosis is present. The reduction in gastric acidity following parietal cell vagotomy that was observed at the 30- and 90-day postoperative test intervals paralleled the reduction seen after more extensive gastric surgical operations. Attempts to explain the mechanism(s) of bacterial proliferation in the upper small bowel following peptic ulcer surgery must therefore take into account the influence of antral-duodenal vagal innervation as well as the bacteriostatic effects of gastric acid.

2894 THE EFFECT OF "HUMANISED" MILKS AND SUPPLEMENTED BREAST FEEDING ON THE FAECAL FLORA OF INFANTS. (Eng.) Bullen, C. L.; Tearle, P. V.; Stewart, M. G. (Public Health Lab., Luton, England). *J. Med. Microbiol.* 10(4):403-443; 1977.

The microbiological and physicochemical properties of fecal specimens from 47 babies on different diets were studied weekly during the first 6 weeks of life. Thirteen infants received breast milk alone, 9 received Cow and Gate Premium milk, 10 received Scientific Milk Adaptation Gold Cap milk, and 15 received breast milk and in the first week of life a supplement of modified cows' milk. The Cow and Gate Premium milk and the Scientific Milk Adaptation Gold Cap milk formulas were cow's milk preparations with the protein and carbohydrate content adjusted to concentrations similar to those of breast milk and with buffering capacities only slightly greater than that of breast milk. An acetate buffer was demonstrated in the feces of over 60% of breast-fed infants during the first 4 weeks of life. No buffer was demonstrated in the feces of either bottle-fed group over the same period. Only 20% of breast-fed infants receiving a supplement produced an acetate buffer in the first week, but this figure increased to 60% by the fourth week. Breast-fed babies produced feces with a low pH (5.1-5.4), high counts of bifidobacteria, and low counts of coliforms, bacteroids, and clostridia; with the exception of acetic acid, there was a notable absence of most volatile fatty acids from these feces. Infants fed Premium milk produced feces with a high pH (5.9-8.0) and a relatively high bifidobacterial count in the first week; thereafter no bacterial species predominated. A wide variety of volatile fatty acids was present in these infants' feces. Infants fed Gold Cap milk produced feces with a high pH (6.4-8.2) and a wide variety of volatile fatty acids; the counts of coliform bacilli and putrefactive bacteria were high, while bifidobacteria counts were low. Breast-fed infants who received a supplement in the first week produced acid feces, but the pH was higher than that of infants fed breast milk alone; the bacterial flora was putrefactive for the first 2 weeks but gradually became fermentative, and although several volatile fatty acids were detected in the feces in the first week they gradually decreased during the following 5 weeks. The results support earlier findings that the supplementation of breast feeding with artificial feeds of high buffering capacities interferes with the establishment of a fermentative bacterial flora and consequently with the development of acidic feces.

2895 COMPARISON OF THE FECAL MICROFLORA OF SEVENTH-DAY ADVENTISTS WITH INDIVIDUALS CONSUMING A GENERAL DIET: IMPLICATIONS CONCERNING COLONIC CARCINOMA. (Eng.) Goldberg, M. J.; Smith, J. W.; Nichols, R. L. (Univ. Illinois Hosp., Chicago, IL). *Ann. Surg.* 186(1):97-100; 1977.

A double-blind study was carried out in 14 Seventh-Day Adventists, who were vegetarians, and in 14 subjects on a general western diet to determine if there are quantitative or qualitative differences in the fecal microflora of vegetarians. No statistically significant differences were identified in the fecal microflora of the two groups. The bacteriologic analysis included total aerobes and total anaerobes as well as each of the major fecal aerobes and anaerobes. This study seems to indicate that the dietary intake of animal fat and protein does not significantly alter the fecal microflora. It does not, however, invalidate the concept that dietary animal fat does increase bile acid degradation within the gastrointestinal tract, a factor that has been related to colon cancer. Future studies should be directed at identifying the factors that may be present in the gastrointestinal tracts of vegetarians that modify the ability of their colonic microflora to degrade bile acids, an essential step in the production of intraluminal carcinogens or cocarcinogens.

2896 STUDIES ON THE PATHOGENICITY OF Yersinia enterocolitica. I. EXPERIMENTAL INFECTION IN RABBITS. (Eng.) Une, T. (Res. Inst., Daiichi Seiyaku Co., Ltd., 2810, Minamifunabori, Edogawa-ku, Tokyo 132, Japan). *Microbiol. Immunol.* 21(7):349-363; 1977.

The pathogenicity of *Yersinia enterocolitica* was analyzed in a model in which rabbits were inoculated intraduodenally with strains isolated from various sources. Pathogenic strains easily penetrated the epithelial linings of the intestinal mucous membrane into the target reticuloendothelial tissues of the intestine, such as the lamina propria and lymph follicles, where they multiplied within mononuclear cells and produced granuloma. Granuloma, in severe infections, underwent necrobiosis and sometimes progressed to ulceration accompanied by colony formation of the organisms. In mild infections, granulomatous lesions were localized in lymph follicles and never progressed to ulceration. Nonpathogenic strains were rapidly excreted without penetration of epithelial linings. These observations suggest that *Y. enterocolitica* should be within the category of invasion-type enteropathogenic bacteria such as *Shigella* and *Salmonella*.

2897 MICROVASCULAR PRESSURES IN RAT INTESTINAL MUSCLE AND MUCOSAL VILLI. (Eng.) Gore, R. W.; Bohlen, H. G. (Coll. Medicine, Univ. Arizona, Tucson, AZ 85724). *Am. J. Physiol.* 233(6): H685-H693; 1977.

Direct pressures were recorded from single innervated microvessels in intestinal muscle, submucosal surface, and mucosal villi of rats to obtain a more complete, quantitative measure of the normal pressure distributions in these regions. Results were compared with existing data from whole-organ, isogravimetric studies. Pressures were recorded with a servo-null transducer; vessel dimensions, with a video device; and relative blood flows in muscle and mucosal regions, with microparticles. When femoral artery pressure was 100-110 mm Hg, the average pressures in first-, second-, third-, and fifth-order muscle and submucosal arterioles were 44.8 ± 1.6, 44.6 ± 2.9, 32.4 ± 2.6, and 26.6 ± 2.0 mm Hg, resp. Pressures in fourth-, second-, and first-order muscle and submucosal venules were 16.2 ± 0.8, 14.6 ± 0.9, and 10.5 ± 0.6 mm Hg, resp.; muscle capillary pressures averaged 23.8 ± 1.5 mm Hg. Average pressures in distributing arterioles, capillaries, and second-order venules in mucosal villi were 30.6 ± 1.8, 13.8 ± 2.2, and 12.8 ± 1.5 mm Hg, resp. Relative mean blood flows were 30 ± 1% in the muscles and 70 ± 1% in mucosal villi. The results show that significant regional differences in capillary pressures exist between intestinal muscle and mucosal layers. Capillary pressures and relative flows were used to calculate a weighted-average capillary pressure of 16.8 mm Hg for the whole intestine, which compares favorably with results from isogravimetric studies, and implies that regions in the intestine may continuously filter or absorb while the whole organ is in fluid balance. These results resolve an apparent discrepancy between previous isogravimetric and microcirculatory experiments, but raise new questions about regional differences in transcapillary fluid exchange. Also, resistance ratios calculated from the data indicate venular resistances in the intestine are more important than previously thought.

2898 ACUTE DISTAL INTESTINAL OBSTRUCTION IN GNOTOBIOTIC RATS: INTESTINAL MORPHOLOGY AND CELL RENEWAL. (Eng.) Ecknauer, R.; Clarke, R. M.; Meyer, H. (Univ. Texas Health Science Center, Post Box 20036, Houston, TX 77025). *Virchows Arch.* [*Cell Pathol.*] 25(2):151-160; 1977.

Intestinal morphology and cell renewal were examined 72 hr following complete mechanical obstruction of the distal small intestine in gnotobiotic rats. The obstruction was produced by ligation 20 cm proximal to the ileocecal valve. Small intestine morphology and epithelial cell renewal were investigated proximal and distal to the site of obstruction. Proximal to the site of obstruction there were minor changes in villus height, base length, and in villus cell number, a large increase in depth and diameter of the crypts, and an approximately threefold increase in cell renewal. Distal to the site of obstruction there were no differences between the intestines of rats with obstruction and sham-operated controls. The apparent lack of secretion by the goblet cells and the reduced number of intra-epithelial leukocytes suggest that the barrier function of the small intestine is impaired in obstruction.

2899 REACTIVE HYPEREMIA AND OXYGEN EXTRACTION IN THE FELINE SMALL INTESTINE. (Eng.) Mortillaro, N. A.; Granger, H. J. (Coll. Medicine, Univ. South Alabama, Mobile, AL 36688). *Circ. Res.* 41(6):859-865; 1977.

Experiments were carried out to determine (a) if vasoregulation during vascular occlusion reflects a myogenic or metabolic mechanism, (b) the mechanisms used by intestinal tissue to reestablish normal blood-tissue O_2 transport following the release of vascular occlusion, and (c) the effect of vascular occlusion on intestinal aerobic metabolism. Arterial flow and oxygen extraction were continuously measured from an *in situ*, denervated loop of cat ileum. Following release of arterial occlusion of varying time periods, oxygen extraction decreased transiently, returning to control levels as the hyperemia subsided. These results suggest that the hyperemia overcompensates in attempting to repay the oxygen deficit and, consequently, oxygen extraction is depressed. In the pump-perfused preparation (constant flow), oxygen extraction rose following the release of arterial occlusion, indicating a shift to oxygen extraction as the mechanism for repaying the oxygen deficit in the absence of hyperemia. Following venous occlusion, reactive hyperemia failed to develop in most cats and, when present, was highly blunted. In addition, oxygen extraction rose transiently suggesting that, as with constant flow, this is the mechanism of oxygen debt repayment in the absence of hyperemia. With venous pressure elevation, a decrease in blood flow was coupled to an increase in oxygen extraction that resulted in an overall increase in calculated oxygen consumption; oxygen extraction progressively increased for each level of venous pressure. Estimated oxygen consumption following occlusion suggests a decrease in oxygen demand during arterial occlusion and an increased demand during venous occlusion. However, during venous occlusion, the myogenic and metabolic control mechanisms would elicit opposite effects. The blunted hyperemic response observed following venous occlusion may result from the net influence of both mechanisms acting in opposition, that is, a myogenic influence modulated by a metabolic one.

2900 EFFECTS OF ARGININE VASOPRESSIN ON CAPILLARY FILTRATION IN THE CAT ILEUM. (Eng.) Quillen, E. W.; Granger, D. N.; Taylor, A. E. (Dept. Physiology and Biophysics, Univ. Mississippi Sch. Medicine, Jackson, MS). *Gastroenterology* 73(6): 1290-1295; 1977.

The effect of local intra-arterial infusion of arginine vasopressin on capillary, interstitial, and lymphatic dynamics of the small intestine was studied in a vascularly perfused segment of cat ileum. Systemic arterial pressure, superior mesenteric arterial pressure, superior mesenteric venous pressure, blood flow, and intestinal volume were continuously monitored. Intestinal lymph flow, lymphatic protein clearance, isovolumetric capillary pressure, capillary filtration coefficient, and vascular resistances were also determined. A dose-response relation was obtained for several parameters, and a dosage of 17.5 mU/kg/min was chosen for more extensive study. At this level, vasopressin increased both systemic and local arterial pressures (from 162 mm Hg and 142 mm Hg, resp., for control levels to 172 mm Hg and 162 mm Hg, resp., while it decreased superior mesenteric venous pressure, capillary pressure, and blood flow. Precapillary, postcapillary, and total vascular resistance were all increased during the vasopressin infusion; however, a greater effect was demonstrated on the precapillary vessels as indicated by an increased pre- to postcapillary resistance ratio. Vasopressin infusion also reduced the capillary filtration coefficient, intestinal volume, lymph flow, and lymphatic protein clearance. The results establish an effect of vasopressin on transcapillary and lymphatic volume flows in the small intestine.

2901 SOME FACTORS INFLUENCING CAECAL ENLARGEMENT INDUCED BY RAW POTATO STARCH IN THE RAT. (Eng.) El-Harith, E. A.; Walker, R.; Birch, G. G.; Sukan, G. (Dept. Biochemistry, Univ. Surrey, Guildford, Surrey GU2 5XH, England). *Food Chem.* 2(4):279-289; 1977.

The phenomenon of cecal enlargement in rats fed raw potato starch as their sole dietary carbohydrate source was examined. The ceca of animals fed a diet containing 71% raw potato starch (total carbohydrate content) were enlarged 800-1,700%. They contained undigested starch, an increased number of microorganisms, and a lower concentration of ions and were of lower pH (5.5) than those of controls (pH 7.0) fed raw maize starch, extracted maize starch, or extracted potato starch. The duodenal contents had a lower specific activity of amylase expressed either as whole duodenal contents or on the basis of duodenal protein, which was also depressed. This finding suggests that the potato starch either: (a) contains an inhibitor of pancreatic amylase, (b) lacks an amylase activating or stabilizing factor, or (c) causes changes in the duodenal secretions. The resistance of potato starch to pancreatic amylase, together with the lower level of amylase in the duodenum, results in undigested starch reaching the cecum, and probably acting as a substrate there for the cecal microflora. Cecal enlargement may result from a homeostatic, adaptive mechanism to control water absorption and osmolality in the cecum.

2902 VASCULAR RESPONSES TO MECHANICAL STIMULATION OF THE MUCOSA OF THE CAT COLON. (Eng.) Fasth, S.; Hulten, L.; Lundgren, O.; Nordgren, S. (Dept. Surgery II, Univ. Goteborg, GoteBorg, Sweden). *Acta Physiol. Scand.* 101(1):98-104; 1977.

Studies were carried out in cats to determine whether a local vasodilator response similar to that in the small intestine could be elicited by mechanical stimulation of the colonic mucosa and to study the role of 5-hydroxytryptamine (5-HT) in the reflex vasodilatation associated with mechanical stimulation of the rectal mucosa. Mechanical stimulation of the mucosa of the proximal colon (by rotating a swab in the colonic lumen at laparotomy) evoked a hyperemia that also could be elicited by severing the autonomic fibers to the colon. Mechanical stimulation of the distal colon produced a hyperemia that was abolished by cutting the pelvic nerves. Afferent pelvic nerve stimulation evoked a response similar to that seen when stimulating the distal colon. Adrenergic and cholinergic receptor blocking agents did not affect the responses. Dihydroergotamine, given in doses that abolished the vascular effects of intra-arterial 5-HT, abolished the hyperemia that occurred following mechanical stimulation of the proximal colon but not that of the distal stimulation. It is concluded that a local nervous vasodilator reflex exists in the proximal colon similar to that which has been previously demonstrated in the small bowel and that the reflex vasodilatation evoked by mechanical stimulation in the distal colon is mediated via the pelvic nerves.

2903 COLONIC BASOPHIL HYPERSENSITIVITY. (Eng.) Askenase, P. W.; Boone, W. T.; Binder, H. J. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *J. Immunol.* 120(1):198-201; 1978.

Contact hypersensitivity reactions were elicited by intraluminal application of dinitrochlorobenzene (DNCB, 500 mg of a 2.5% solution) to the colon of guinea pigs. Some of the resulting lesions contained large infiltrates of basophils. These colonic basophil hypersensitivity reactions were accompanied by systemic sensitization and were not seen in nonspecific colonic inflammatory responses induced by croton oil. The heterogenous immune inflammatory responses induced in the colon by DNCB contact sensitivity may serve as a model for the study of inflammatory bowel disease.

2904 CLINDAMYCIN-ASSOCIATED COLITIS DUE TO A TOXIN-PRODUCING SPECIES OF *Clostridium* IN HAMSTERS. (Eng.) Bartlett, J. G.; Onderdonk, A. B.; Cisneros, R. L.; Kasper, D. L. (Veterans Admin. Hosp., Boston, MA 02130). *J. Infect. Dis.* 136(5):701-705; 1977.

Clindamycin-associated enterocolitis was studied in hamsters to determine whether there is a transmissible agent involved in this entity. The disease could be transferred by cecal contents and filtrates of cecal contents (pore size of filter, 0.02 μm) obtained from animals after the i.m. administration of clindamycin (6 mg/day). Subsequent work showed that enterocolitis could be produced with broth cultures of a species of *Clostridium* recovered from cecal contents of animals with clindamycin-induced disease. The cell-free supernatant of this strain also caused enterocolitis. Cecal contents from animals with clindamycin-induced disease incubated with gas gangrene antitoxin failed to cause intestinal lesions. These experiments indicate that clindamycin-associated colitis in hamsters is due to a clindamycin-resistant, toxin-producing strain of *Clostridium*.

2905 GASTROINTESTINAL AND SYSTEMIC TOXICITY OF FECAL EXTRACTS FROM HAMSTERS WITH CLINDAMYCIN-INDUCED COLITIS.

(Eng.) Rifkin, G. D.; Silva, J., Jr.; Fekety, R. (Dept. Internal Medicine, Univ. Michigan, Ann Arbor, MI). *Gastroenterology* 74(1): 52-57; 1978.

The feces of clindamycin-treated hamsters were examined for the presence of toxic substances. Clindamycin (100 mg/kg) induced enterocolitis. Suspensions derived from cecal contents of clindamycin-treated animals induced a hemorrhagic ileocecitis and death within 2 to 4 days after being given orogastrically to other hamsters. The i.p. injection of sterile filtrates of these suspensions produced an exudative peritonitis, intra-abdominal hemorrhages, and death of 80-100% of hamsters within 1 day. These effects were not seen with the i.p. injection of clindamycin or endotoxin, only small amounts of which were present in the filtrate. Incubation of the filtrate *in vitro* with polyvalent clostridial antitoxin neutralized its toxicity. *In vitro* incubation of the filtrate with normal equine serum did not reduce its *in vivo* toxicity. The toxic substance(s) contained in the filtrate was heat-labile and produced morphological changes in Y-1 adrenal cell cultures characteristic of heat-labile enterotoxins. Cecal filtrates obtained from saline-treated animals produced none of these effects. These preliminary studies suggest that enterotoxin-like substances, possibly produced by clostridia, may play an important role in the pathogenesis of clindamycin-induced colitis in the hamster.

2906 EXPERIMENTAL HAMSTER ENTERITIS: AN ELECTRON MICROSCOPIC STUDY.

(Eng.) Frisk, C. S.; Wagner, J. E. (Unit Comparative Medicine, Univ. Minnesota, Minneapolis, MN). *Am. J. Vet. Res.* 38 (11):1861-1868; 1977.

In an attempt to clarify the relationship of an intracellular organism that has been identified within the ileal epithelial cells in animals with hamster enteritis (HE) to the pathogenesis of HE, electron microscopic studies of absorptive epithelial cells were carried out in normal hamsters, hamsters with naturally occurring HE, and in hamsters with experimentally induced HE. HE was experimentally produced in weanling hamsters by the p.o. inoculation of healthy hamsters with suspensions of ilea obtained from hamsters with HE. Control groups of hamsters were inoculated p.o. with suspensions of ilea from healthy hamsters. Ilea from 6 control hamsters, 31 hamsters with experimentally produced HE, and 4 hamsters with naturally occurring HE were studied. Ultrastructural changes were not observed in the absorptive epithelium of control animals. Two different intracytoplasmic bacterial organisms were observed in epithelial cells of hamsters with experimentally produced HE. Organisms that were observed early in the disease process were identified as *Escherichia coli*. Organisms ultrastructurally similar to *Campylobacter* species were observed later in the disease and were only within hyperplastic epithelial cells. The hyperplastic ileal epithelium of hamsters with naturally occurring HE contained campylobacter-like organisms. The results suggest that a synergism between two bacterial organisms may be responsible for the lesions of HE: an enteropathogenic, cell-invasive *E. coli* causing acute enteritis, and small organisms (possibly *Campylobacter* species), which are responsible for the marked ileal cell hyperplasia of HE.

2907 IMMUNOHISTOCHEMISTRY OF CARCINOEMBRYONIC ANTIGEN: CHARACTERIZATION OF CROSS-REACTIONS WITH OTHER GLYCOPROTEINS.

(Eng.) Isaacson, P.; Judd, M. A. (General Hosp., Southampton, England). *Gut* 18(10):779-785; 1977.

In the course of demonstrating carcinoembryonic antigen (CEA) in normal human small intestine, cross-reactivity of specific antiserum against RBC, vascular endothelium, and Paneth cell granules was noted. Pretreatment of sections with periodic acid eliminated these cross-reactions without affecting the staining of CEA, indicating that the antigenic determinants shared between CEA and other glycoproteins are in the carbohydrate portion of the molecules. These findings emphasize that immunohistochemical results should be regarded with caution, even when they are apparently well controlled.

2908 THE INTERACTION OF DIETARY FIBERS AND CHOLESTEROL UPON THE PLASMA LIPIDS AND LIPOPROTEINS, STEROL BALANCE, AND BOWEL FUNCTION IN HUMAN SUBJECTS.

(Eng.) Raymond, T. L.; Connor, W. E.; Lin, D. S.; Warner, S.; Fry, M. M.; Connor, S. L. (Univ. Oregon Health Sciences Center, Portland, OR 97201). *J. Clin. Invest.* 60(6):1429-1437; 1977.

To identify any metabolic effects of dietary fiber upon cholesterol metabolism in man, six adult volunteer subjects were given eucaloric cholesterol-free formula diets, with and without added dietary fiber, for two 4-week periods. Dietary fiber consisted of 60 g of plant cell wall material (or 16 g of crude fiber) derived from corn, beans, bran, pectin, and purified cellulose. This provided about five times the fiber intake of the typical American diet. The addition of fiber to the cholesterol-free diet did not change either the plasma cholesterol level (171 ± 21 to 167 ± 18 mg/dl) or the triglyceride level (103 ± 39 to 93 ± 27 mg/dl). The excretion of both endogenous neutral steroids and bile acids were unchanged with fiber (505 ± 41 to 636 ± 75 mg/day and 194 ± 23 to 266 ± 47 mg/day, resp.). However, total fecal steroid excretion was increased (699 ± 29 to 902 ± 64 mg/day, $p<0.025$). With fiber, intestinal transit time was decreased

(59 ± 9 to 35 ± 8 hr, $p<0.005$), and both the wet and dry stool weights were greatly increased. A second group of six subjects received similar diets containing 1,000 mg cholesterol derived from egg yolk. The addition of fiber to the 1,000-mg cholesterol diet did not alter either plasma cholesterol level (233 ± 26 to 223 ± 36 mg/dl) or triglyceride level (102 ± 19 to 83 ± 11 mg/dl). The excretion of endogenous neutral steroids (618 ± 84 to 571 ± 59 mg/day), of bile acids (423 ± 122 to 401 ± 89 mg/day), and of total fecal steroids (1,041 ± 175 to 972 ± 111 mg/day) were unchanged by fiber. The absorption of dietary cholesterol was not altered when fiber was added to the 1,000-mg cholesterol diet (44.0 ± 3.3 to 42.9 ± 2.5%). A two-way analysis of variance utilizing both groups of subjects indicated a significant ($p<0.001$) effect of dietary cholesterol upon the plasma cholesterol concentration. A large quantity of dietary fiber from diverse sources has little or no effect upon the plasma lipids and sterol balance in man, in spite of the fact that intestinal transit time and stool bulk changed greatly.

2909 REMOVAL OF GASTRIN BY VARIOUS ORGANS IN DOGS. (Eng.) Strunz, U. T.; Walsh, J. H.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Bldg. 115, Rm. 115, Los Angeles, CA 90073). *Gastroenterology* 74(1):32-33; 1978.

The role of various organs in gastrin metabolism was studied in dogs. In six anesthetized dogs receiving 400 pmol/kg/hr of natural human little gastrin i.v., blood samples for radioimmunoassay of gastrin were taken repeatedly from a carotid artery, jugular vein, femoral vein, renal vein, and mesenteric vein. The calculated removal of gastrin in a single passage through these four vascular beds ranged from 21% to 30% and did not differ significantly among them. In six additional dogs, the carotid arterial to hepatic venous removal was 40%. It is concluded that the percentage removal of gastrin is about the same in all of the major vascular beds of the body.

DIAGNOSTIC PROCEDURES

2949 DETERMINATION OF $^{14}CO_2$ IN BREATH AND ^{14}C IN STOOL AFTER ORAL ADMINISTRATION OF CHOLYL-1-[^{14}C]GLYCINE: CLINICAL APPLICATION.

(Eng.) Roda, A.; Roda, E.; Aldini, R.; Mazzella, G.; Festi, D.; Sama, C.; *et al.* (Univ. Bologna, Inst. Chemistry G. Ciamician, 40100 Bologna, Italy). *Clin. Chem.* 23(11):2127-2132; 1977.

A $^{14}CO_2$ breath test for bile acid deconjugation was developed, and the method was validated in 20 patients with intestinal bacterial overgrowth and 20 controls. $^{14}CO_2$ is measured in the breath after cholyl-1-[^{14}C]glycine administration (5 µCi, 100 g/l ethanolic solution, 5 ml, p.o.). The mean $^{14}CO_2$ output/24 hr was 11.0 ± 5.2% in controls and 54.2 ± 14.0% in bacterial overgrowth patients ($p<0.001$). The $^{14}CO_2$ excretion rate in 12 hr, when normalized to 100% of the dose at the 12th hr, gave an even finer discrimination between the two groups (no false responses). ^{14}C in stool, analyzed in 20 malabsorption patients and 20 controls by two different techniques, was 6.6 ± 4% and 31.38 ± 21.7%, resp. Bile acid malabsorption was in reasonable agreement ($r=0.67$) with percentage of "chenoid" (chenodeoxycholic acid plus ursodeoxycholic acid) in the stool by gas-liquid chromatography; a poorer correlation was observed when "chenoid" plus "choloid" (cholic acid plus its epimers) were plotted versus ^{14}C in stool ($r=0.57$, $n=15$).

2950 INTESTINAL ACTIVITIES OF TRYPSIN, LIPASE, AND PHOSPHOLIPASE AFTER A TEST MEAL: AN EVALUATION OF 474 EXAMINATIONS.

(Eng.) Ihse, I.; Arnesjo, B.; Kugelberg, C.; Lilja, P. (Dept. Surgery, Univ. Lund, S-221 85 Lund, Sweden). *Scand. J. Gastroenterol.* 12(6):662-668; 1977.

The value of indirect stimulation of the pancreas by a test meal as a routine pancreatic function test was investigated by comparing trypsin, lipase, and phospholipase concentrations in intestinal aspirates from 452 patients. Trypsin was determined in 452 subjects, lipase in 117, and phospholipase in 57. Following meal stimulation, trypsin levels were subnormal (<37 U/ml) in 88% of the 74 patients with chronic pancreatic diseases; the lipase activity was subnormal (<185 U/ml) in 80% of those with pancreatic disease, while the phospholipase activity was low in 81% of patients with chronic pancreatic disease. The outcome of repeated trypsin tests was completely consistent in 20 of 22 patients. Calculations of ratios between the enzymes studied suggested that lipase was the enzyme most susceptible to pancreatic damage. In 29 cases of celiac disease and in 18 cases in which Polya gastric resection had been performed, the decrease of the intestinal lipase concentrations was more marked than that of the other enzymes. In 9% of the cases of chronic pancreatic insufficiency, the diagnosis would have been overlooked if either lipase or trypsin had been the only enzyme determined. Enzyme determination following meal stimulation is reliable, simple, physiological, and inexpensive, and it is recommended as a routine test of the pancreatic function.

2951 TECHNIQUE FOR MICRODISSECTION AND MEASUREMENT IN BIOPSIES OF HUMAN SMALL INTESTINE.

(Eng.) Ferguson, A.; Sutherland, A.; MacDonald, T. T.; Allan, F. (Gastrointestinal Unit, Univ. Edinburgh, Edinburgh EH4 2XU, Scotland). *J. Clin. Pathol.* 30(11):1068-1073; 1977.

A microdissection and measurement technique adapted for biopsy of human small intestine is described. The technique was applied to the measurement of villi, crypts, and crypt mitotic counts in 90 specimens of normal small intestinal tissue. Specimens fixed in alcohol and acetic acid are Schiff stained in bulk. Villi and crypts are then dissected out under a dissecting microscope, placed under a coverslip, examined, measured, and the number of mitoses in individual crypts counted. With this method, specimens of normal small intestine were found to have villi 500 µm to 1,100 µm long and crypts 150 µm to 300 µm. These values were double those obtained when measuring sections of the same specimens stained with hematoxylin and eosin. The mean number of mitoses per crypt in normal duodenum and jejunum ranged from 1 to 12, and most of the cells in mitosis were in prophase or telophase. This rapid, sensitive, and inexpensive technique complements the available methods of measuring small intestinal architecture.

2952 A NEW HISTOCHEMICAL TECHNIQUE OF USE IN THE INTERPRETATION AND DIAGNOSIS OF ADENOCARCINOMA AND VILLOUS LESIONS IN THE LARGE INTESTINE.

(Eng.) Culling, C. F. A.; Reid, P. E.; Worth, A. J.; Dunn, W. L. (Dept. Pathology, Univ. British Columbia, Vancouver, British Columbia, Canada). *J. Clin. Pathol.* 30(11):1056-1062; 1977.

The periodic acid-thionin Schiff/potassium hydroxide/periodic acid-Schiff (PAT/KOH/PAS) procedure was used to investigate the histochemical staining characteristics of the mucins found in adenocarcinoma and villous lesions of the large intestine. The 46 blocks examined represented 58 lesions from 37 patients, all of whom had had resections for carcinoma of the colon. In contrast to normal colon, none of the adenocarcinomas stained red with the PAT/KOH/PAS. With two exceptions, the poorly and moderately differentiated adenocarcinomas stained blue, whereas of the well differentiated lesions half were blue and half purple. The malignant villous lesions demonstrated the same trends, although a larger percentage were purple. None of the benign lesions stained blue. Malignancy in the colon is accompanied by an increase in blue staining in the PAT/KOH/PAS technique, and such staining may be of value in the interpretation of highly atypical adenoma where it might identify the onset of malignancy. This change in staining indicates a distinct alteration in the chemistry of the mucins, which are interpreted to be a reduction in the degree of side chain O-acylation of their constituent sialic acids.

2953 PHENOTYPIC MARKERS IN HUMAN SKIN FIBROBLASTS AS POSSIBLE DIAGNOSTIC INDICES

OF HEREDITARY ADENOMATOSIS OF THE COLON AND RECTUM. (Eng.) Kopelovich, L. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021). *Cancer* 40(5, Suppl.):2534-2541; 1977.

The growth abnormalities of cultured human skin fibroblasts derived from normal-appearing cutaneous biopsies from subjects with hereditary adenomatosis of the colon and rectum (ACR) genotypes and from a portion of their clinically asymptomatic ACR progeny (first filial generation) are described together with the differential susceptibility of these fibroblasts to transformation by Kirsten murine sarcoma virus. These skin fibroblasts, but not cells derived from unaffected individuals, showed lack of contact inhibition, decreased serum requirement for growth, elevated levels of plasminogen activator (46.7 ± 6.5%), and alterations in the intracellular distribution of actin cables; they did not, however, grow in the absence of anchorage, nor did they form palpable tumors in congenitally athymic BALB/c *nu/nu* mice, and they were normal with regard to cholesterol feedback regulation. Skin fibroblasts from ACR subjects were 100- to 1,000-fold more susceptible to transformation by the Kirsten murine sarcoma virus than were normal cells. The virally transformed skin fibroblasts were anchorage-independent and formed tumors in athymic mice. These growth abnormalities represent steps in the changing phenotypic expression of cells undergoing neoplastic transformation. Identification of abnormal expressions associated with oncogenesis may facilitate their use as diagnostic indices for the detection of latent forms of colon cancer in man.

2954 COLORECTAL CANCER DIAGNOSIS BY A DIRECT LEUKOCYTE MIGRATION TEST USING A PANEL OF TUMOUR EXTRACTS.

(Eng.) Zoller, M.; Matzku, S.; Schulz, U. (German Cancer Res. Center, Heidelberg, W. Germany). *Cancer Immunol. Immunother.* 2(4):257-265; 1977.

Experiments were carried out to determine if the modified direct leukocyte migration test, using a panel of tumor extracts, is as useful in the detection of colorectal cancer as of gastric cancer and to study the results of this test after surgery and when metastases occurred. Peripheral WBC were pulsed with a high dose (2.5 and 0.5 mg/ml) of 3 M KCl extracts from five different colorectal tumors as well as with one 3 M KCl extract of normal colonic mucosa. Patients showing a pathological migration index (≤ 0.80 and ≥ 1.17) with three or more of the five tumor extracts were considered as "positives." With this test, 55/59 of patients with colorectal carcinomas were reactive, irrespective of the tumor stage, while only 2/27 patients with nonmalignant colorectal diseases showed a positive reaction. Patients with malignant and nonmalignant diseases of other organs were reactive in 2-3% of cases. No positive reactivity was observed with WBC from 37 healthy volunteers. When WBC were pulsed with the normal colonic mucosal extract, a pathological migration index was found in about 20% of colorectal cancer patients, but not in healthy volunteers. Evaluating 10 single-tumor extracts individually, the reactivity of cancer patients' WBC ranged from 65-89% of tests, but this difference was not statistically significant. WBC from healthy volunteers showed a pathological migration index with the different extracts in 0-6% of tests. With the leukocyte migration test, tumors of the colon, sigmoid, or rectum could not be distinguished. Patients bearing tumors in any part of the large bowel showed pathological leukocyte migration with extracts of colon, sigmoid, and rectal tumors. When the cross-reactivity study was extended to tumors of the gastrointestinal tract, it was found that patients with colorectal tumors were reactive, in a high percentage of tests, with extracts of gastric tumors, but gastric as well as esophageal and pancreatic cancer patients' WBC only reacted occasionally with colorectal tumor extracts. In the follow-up study, a positive reactivity was still found 10-14 days after surgery in 27 of 31 patients. After more than 2 months, the frequency of positive reactivity decreased to 10 of 70 cases. Patients with local recurrence or metastases exhibited positive reactivity in six of seven cases. The panel modification of the leukocyte migration test is highly sensitive and specific in the study of colorectal tumors, and it may be valuable in follow-up studies after colorectal tumor excision.

2955 THE DISTRIBUTION OF GASTRIC ULCERS: DOUBLE CONTRAST BARIUM MEAL AND ENDOSCOPY FINDINGS.

(Eng.) Stevenson, G. (McMaster Univ. Medical Center, 1200 Main St. West, Hamilton, Ontario, Canada). *Clin. Radiol.* 28(6):617-624; 1977.

To evaluate conflicting findings in the radiologic and endoscopic diagnosis of ulcers in various areas of the stomach, 1,000 consecutive double-contrast barium meals and 424 consecutive upper gastrointestinal endoscopic examinations were reviewed. Seventy gastric ulcers were found radiologically in 56 patients, and 82 gastric ulcers were found endoscopically in 70 patients. Fifty-five percent of radiologically and 53.6% of endoscopically diagnosed ulcers were located in the mid or upper body of the stomach. This distribution is contrary to previous radiological findings with the traditional barium meal. Age did not seem to be a major factor. The double-contrast meal and, in particular, the left anterior oblique view with the head elevated, display *en face* the lesser curve of the upper body around the cardia where many benign ulcers and carcinomas arise.

2956 LIVER BIOPSY: COMPLICATIONS IN 1000 INPATIENTS AND OUTPATIENTS.

(Eng.) Perrault, J.; McGill, D. B.; Ott, B. J.; Taylor, W. F. (Mayo Clinic, 200 First St. SW, Rochester, MN 55901). *Gastroenterology* 74(1):103-106; 1978.

Risk factors were evaluated prospectively in 829 outpatients and 171 inpatients who underwent liver biopsy. The two groups were similar, except that the outpatient group had a higher percentage of patients with hepatitis-cirrhosis and a lower percentage with neoplasia when compared with the inpatient group ($p<0.01$). The inpatient group had more relative contraindications ($p<0.01$). Among the total 1,000 patients, none died and none required laparotomy. If moderate to severe pain, hypotension, or both developed (5.9%), they first became manifest during a 3-hr period of observation after biopsy. Forty-four outpatients (5.3%) were hospitalized; 39 were dismissed within 36 hr and 5 within 4 days. Complications were more often experienced by those with relative contraindications ($p<0.05$) and increased number of passes ($p<0.01$). Inpatients with hepatitis-cirrhosis experienced more complications ($p<0.05$) than did patients with other diagnoses (12.8% versus 3.8%). Complications were not related to type of needle, site of entry, or experience of operator. Liver biopsy as an outpatient procedure is safe if facilities are available for 3 hr of observation and hospital support; 5% of patients will require immediate hospitalization.

2957 CLINICAL INDICATIONS AND ACCURACY OF GRAY SCALE ULTRASONOGRAPHY IN THE PATIENT WITH SUSPECTED BILIARY TRACT DISEASE.

(Eng.) Prian, G. W.; Norton, L. W.; Eule, J., Jr.; Eiseman, B. (Univ. Colorado Medical Center, Denver, CO). *Am. J. Surg.* 134(12):705-711; 1977.

The clinical efficacy of gray scale, B-mode ultrasonography was evaluated in patients with suspected biliary tract disease. One hundred patients underwent gray scale cholecystosonography (GSCS) and had diagnostic confirmation by p.o. cholecystogram (OCG) and/or operation. Ultrasonography demonstrated the gallbladder in 94 of the 100 patients; 2 patients had had previous cholecystectomy, and 3 of the 4 remaining patients had documented stones with no confirmation of a nonvisualizing OCG in the other patient. Among the 88 patients with OCG, GSCS findings correlated in 91% (2% false-positive; 7% false-negative). Among the 43 operative patients, GSCS was proven correct in 91% (no false positive; 9% false-negative). Of 12 patients with jaundice, GSCS correlated with operative findings in 75% (no false-positive; 25% false-negative). Diagnostic errors occurred in patients with very small biliary calculi, particularly when a single stone was impacted in the cystic duct. Failure to identify the gallbladder with ultrasound signifies probable cholelithiasis in the patient without previous cholecystectomy. It is concluded that: (a) GSCS is most useful when jaundice or acute illness precludes conventional studies; (2) GSCS provides an inexpensive, quick, accurate means of diagnosing cholelithiasis with a very high specificity (97%) and moderate sensitivity (88%); and (c) GSCS is the optimal diagnostic procedure for evaluating the biliary tract in the acutely ill, jaundiced, vomiting, allergic, and/or pregnant patient.

2958 GRAY SCALE ULTRASONOGRAPHY OF THE GALLBLADDER: AN EVALUATION OF ACCURACY AND REPORT OF ADDITIONAL ULTRASOUND SIGNS.

(Eng.) Anderson, J. C.; Harned, R. K. (Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB 68105). *Am. J. Roentgenol.* 129(6):975-977; 1977.

The results of ultrasound examinations of 76 patients with suspected gallbladder disease were compared with radiographic, surgical, and pathologic findings to determine the accuracy of the ultrasound examinations. In 13 patients, the gallbladder was not visualized by ultrasound. Diagnosis of the presence or absence of gallstones was correctly made by ultrasound in 56 of 63 visualized gallbladders, for an accuracy rate of 89%. A high proportion of nonvisualized gallbladders (10/13) contained gallstones. Previously unreported ultrasound findings of a stone impacted in the proximal cystic duct and findings of a collection of bile in the lesser sac associated with cholelithiasis and choledocholithiasis are illustrated.

2959 GRAY-SCALE ULTRASOUND OF BILIARY TRACT DISEASE: A CORRELATIVE STUDY WITH PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY.

(Eng.) Cooperberg, P.; Ayre-Smith, G.; Garrow, D. G. (Vancouver General Hosp., Univ. British Columbia, Vancouver, British Columbia V5Z 1M9, Canada). *J. Can. Assoc. Radiol.* 28(4):237-242; 1977.

The specificity and sensitivity of gray-scale ultrasound (US) in the detection of dilatation of intrahepatic bile ducts, as compared to percutaneous transhepatic cholangiography (PTC) was tested in 47 patients who were studied prospectively by both techniques. In 23 patients demonstrated by PTC to have dilated intrahepatic ducts, 18 were detected by US. Of the 11 patients shown to have nondilated ducts by PTC, all were accurately predicted by US. In 13 cases in which PTC was unsuccessful, the US study showed 12 to be nondilated and one to be mildly dilated. Because ultrasound is a noninvasive technique, it should be the primary imaging technique in the evaluation of possible extrahepatic obstructive jaundice.

2960 SERUM BILE ACIDS IN THE DIAGNOSIS OF HEPATOBILIARY DISEASE.

(Eng.) Pennington, C. R.; Ross, P. E.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Gut* 18(11): 903-908; 1977.

The value of serum bile acids (SBA) in the diagnosis of hepatobiliary disease was investigated in 14 controls, 16 patients with cirrhosis, 15 with extrahepatic obstruction, 12 with viral hepatitis, 8 with neoplasia, 7 with infectious mononucleosis, and 14 with miscellaneous diseases. A modified gas-liquid chromatographic method was used, with an overall coefficient of variation of ±11% in the control range. Serum was obtained after a 12-hr fast, and 2 hr after a fatty meal from 73 patients and 14 control subjects. In controls, the total fasting SBA of 2.17 ± 0.86 μM increased significantly ($p<0.001$) to 3.81 ± 1.14 μM after a meal. All icteric patients had raised SBA, but, in 23 anicteric patients, there was no significant difference in the detection of chronic liver disease by fasting SBA, postprandial SBA, aspartate aminotransferase, or gamma glutamyl transpeptidase. Compared with controls, serum in patients contained proportionately less deoxycholic acid ($p<0.001$); there was proportionately more cholic acid in extrahepatic obstruction ($p<0.001$) and proportionately more chenodeoxycholic acid in patients with cirrhosis, viral hepatitis, and neoplasia ($p<0.001$). In controls, the fasting cholic:chenodeoxycholic acid ratio ranged from 0.5-1.0, and differed significantly ($p<0.001$) from patients with extrahepatic obstruction 0.96-3.6, and cirrhosis 0.1-0.5. It is concluded that serum bile acids measured by sensitive methods can provide useful diagnostic information.

2961 FASTING AND POSTPRANDIAL SERUM BILE ACIDS AS A SCREENING TEST FOR HEPATOCELLULAR DISEASE. (Eng.) Angelico, M.; Attili, A. F.; Capocaccia, L. (Dept. Internal Medicine, Univ. Rome, Rome, Italy). *Am. J. Dig. Dis.* 22(11):941-946; 1977.

The significance of postprandial serum bile acid estimation as a test of liver function was evaluated in 19 normal subjects, 20 patients with cirrhosis, 10 with acute hepatitis, 4 with resolving viral hepatitis, and 6 with chronic active hepatitis. A gas-chromatographic method was used. One healthy subject had postprandial serum bile acid levels above the normal range, while seven patients with liver disease had postprandial levels within normal limits. Of the latter group, two had chronic active hepatitis in remission and three had resolving viral hepatitis. Significant correlations were seen between serum bile acid levels and most of the conventional liver function tests (total bilirubin, conjugated bilirubin, alkaline phosphatase, γ-glutamyl-transferase, cholinesterase, Hepato-Quick, and SGPT; correlation coefficients for postprandial serum bile acid levels and these liver function tests were 0.702, 0.663, 0.424, 0.067, -0.373, -0.379, 0.684, and 0.707, resp.; all significant at $p<0.001$ or $p<0.01$ except that for γ-glutamyl-transferase). These data indicate that the postprandial serum bile acid determinations is better than any of the other conventional tests taken separately, but no better than their combined use. No significant modification of the cholic acid/chenodeoxycholic acid ratio was observed between the fasting and the postprandial determinations.

2962 RADIOIMMUNOASSAY OF SERUM-CONJUGATED DEOXYCHOLIC ACID. (Eng.) Matern, S.; Krieger, R.; Hans, C.; Gerok, W. (Medizinische Universitatsklinik, Hugstetter Str. 55, D-78000 Freiburg i.Br., W. Germany). *Scand. J. Gastroenterol.* 12(6):641-647; 1977.

A specific, sensitive, and reliable radioimmunoassay for serum-conjugated deoxycholic acid is described, in which antiserum is obtained after immunization of rabbits with a deoxycholic acid-bovine serum albumin conjugate. The displacement curve of glyco[^{3}H]-deoxycholic acid was linear on a logit-log plot from 7.5 to 320 pmol of unlabeled glycodeoxycholic acid. At 50% displacement of bound label, the cross-reactivity of taurodeoxycholic acid was 100%, deoxycholic acid 30%, taurocholic acid 3%, and glycocholic acid 2%. No cross-reactivity was observed with free cholic acid, conjugated or free chenodeoxycholic acids, and conjugated or free lithocholic acids. Fasting serum-conjugated deoxycholic acid concentrations in 10 healthy volunteers ranged from 0.18 to 0.92 μM. Over a period of 5 hr following 0.5 g p.o. cholate administration, the serum-conjugated deoxycholic acid concentration did not change in five fasting healthy subjects, whereas an initial increase of serum cholic acid was observed.

2963 RADIOIMMUNOASSAY OF SULFATED LITHOCHOLATES. (Eng.) Cowen, A. E.; Korman, M. G.; Hofmann, A. F.; Turcotte, J.; Carter, J. A. (Royal Brisbane Hosp., Brisbane, Australia). *J. Lipid Res.* 18(6):698-703; 1977.

A sensitive, rapid radioimmunoassay for sulfated species of lithocholic acid (sulfolithocholylglycine, sulfolithocholyltaurine, and sulfolithocholic acid) was developed and used to measure the total concentration of sulfated lithocholates in the sera of 50 healthy human subjects. Sulfolithocholylglycine was conjugated to bovine serum albumin by a carbodiimide procedure, and the reaction product, emulsified in Freund's adjuvant, was injected intracutaneously into rabbits. The antiserum obtained was capable of binding 40% of [^{3}H]sulfolithocholylglycine at 1:1,000 dilution. The assay featured a 2-hr binding step at 42 C followed by precipitation of bound tracer with polyethylene glycol at 4 C. The assay can be used with 0.1 ml of serum and was reproducible. The antibody had little affinity for the 3-sulfate of cholic or chenodeoxycholic acid, a number of steroid sulfates, or unsulfated bile acids. In the healthy subjects, mean fasting-state serum levels of immunoreactive sulfated lithocholyl conjugates (+sulfated lithocholate) was 1.6 ± 0.1 μM; based on results with a separate radioimmunoassay for unsulfated lithocholyl conjugates, most of the lithocholate in serum in healthy humans is present in sulfated form.

2964 RADIOIMMUNOASSAY OF UNSULFATED LITHOCHOLATES. (Eng.) Cowen, A. E.; Korman, M. G.; Hofmann, A. F.; Turcotte, J.; Carter, J. A. (Royal Brisbane Hosp., Brisbane, Australia). *J. Lipid Res.* 18(6):692-697; 1977.

A new radioimmunoassay for total unsulfated species of lithocholate (lithocholylglycine, lithocholyltaurine, and lithocholate) in human serum is described, and results obtained with this method in the sera of healthy subjects are reported. Antiserum was raised in rabbits by injection of lithocholylglycine coupled to bovine serum albumin (prepared by a carbodiimide method) and emulsified in complete Freund's adjuvant; antisera capable of measuring 40-120 pmol at 1:400 dilution were obtained. The tracer was [11,12-^{3}H]lithocholylglycine. The radioimmunoassay features a 2-hr binding step at 42 C and a 1-hr separation step using polyethylene glycol. The antibody had the following relative specificities: lithocholylglycine and lithocholyltaurine, 1; lithocholate, 1.5; chenodeoxycholylglycine, 20; and deoxycholylglycine, 55. There was no binding of various other free or conjugated sulfated and unsulfated bile acids. The mean fasting-state level in 50 subjects was 0.3 µmol/l (0.14 µg/ml), but 11 of the 50 subjects had levels too low to measure by this technique. The technique is simple, rapid, and precise, and should permit the measurement of unsulfated lithocholate species in health and in some instances of liver disease.

2965 RADIOLOGICAL TECHNIQUE IN THE STUDY OF THE CEPHALO-PANCREATIC AREA WITH SPECIAL REFERENCE TO HYPOTONIC DUODENOGRAPHY. (Ita.) Contri, D.; Marchisio, V.; Biasio, A.; Bettoni, C. (Spedali Civili di Bescia, Piazza Spedali Civili, I-25100 Brescia, Italy). *Radiol. Med. (Torino)* 63(1):33-40; 1977.

GASTROINTESTINAL DISEASES

ESOPHAGUS

3019 ULTRASTRUCTURAL CHANGES OF THE VAGUS NERVE IN ESOPHAGEAL ACHALASIA. (Spa.) de la Fuente, A.; Garcia-Calvo, M.; Ramon y Cajal, S.; Paya, J. M.; Cuesta, G. (Hospital Clinico de San Carlos, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 51(6):659-666; 1977.

Ultrastructural changes were studied in biopsy specimens of the vagus nerves from five patients with diagnostically established esophageal achalasia. The micrograms showed the predominance of amyelinated fibers; myelinated fibers were scarce and degenerated. The electron micrographs of the myelinated fibers showed frequent demyelinization with conservation of the axon and Schwann's cells with prominent nuclei and abundant cytoplasm rich in granular endoplasmic reticulum. Some Schwann's cells underwent complete demyelinization. The amyelinated fibers had only one or two axons. Atrophy of Schwann's cells was seen in some amyelinated fibers. The endoneurium was usually rich in collagen fibers, and macrophages with large cytoplasm of irregular shape containing abundant lysosomes and well-developed Golgi complexes were seen occasionally in the interfibrillar space. The findings indicate that alterations of the vagus nerve are obligatory in esophageal achalasia. These alterations appear to be of extra-esophageal origin and of degenerative and progressive character, while the lesions in the esophageal wall are secondary.

3020 DIAGNOSIS OF SYMPTOMATIC GASTROESOPHAGEAL REFLUX BY PROLONGED MONITORING OF LOWER ESOPHAGEAL pH. (Eng.) Irvin, T. T.; Perez-Avila, C. (Royal Infirmary, Sheffield S6 3DA, England). *Scand. J. Gastroenterol.* 12(6):715-720; 1977.

To evaluate the use of prolonged monitoring of the lower esophageal pH in the diagnosis of gastroesophageal reflux, the lower esophageal pH was continuously monitored for 15 hr in 10 asymptomatic subjects and 27 patients with symptoms of gastroesophageal reflux, and the pH measurements in symptomatic patients were compared with the results of other esophageal investigations. Symptomatic patients had significantly longer periods of reflux in the pH test (93.7 ± 28.9 min at pH ≤4 and 204.8 ± 36.6 min at pH ≤5) than asymptomatic subjects (4.8 ± 1.6 min at pH ≤4 and 10.7 ± 3.2 min at pH ≤5, $p<0.01$), but there was no significant correlation between the pH measurements and the results of esophageal manometry, acid perfusion, and acid clearing tests. Ten patients had evidence of esophagitis at esophagoscopy, but there was no correlation between pH measurements and the findings at esophagoscopy. Two patients with esophagitis had no evidence of reflux in the pH monitoring test. The results indicate that the pH monitoring test is useful in the diagnosis of gastroesophageal reflux in patients who do not have endoscopic signs of esophagitis. However, negative pH tests do not exclude the diagnosis of symptomatic reflux, and it appears that the test has no value in assessing the severity of esophageal inflammation.

3021 QUANTITATION OF GASTROESOPHAGEAL REFLUX BEFORE AND AFTER THERAPY USING THE GASTROESOPHAGEAL SCINTISCAN. (Eng.) Malmud, L. S.; Fischer, R. S. (Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *South. Med. J.* 71(Suppl. 1): 10-15; 1978.

The scintiscanning technique was used to detect and quantitate gastroesophageal reflux before and after therapy in 30 patients with symptomatic heartburn and a positive reflux test and in 20 normal controls. In 10 patients, the reflux was studied both with and without a tube assembly with an isotopic marker positioned at the lower esophageal sphincter (LES). The scintiscans were obtained after the instillation of 300 ml of isotonic saline with 100 to 300 μCi ^{99m}Tc sulfur colloid. It was shown that reliable scintiscans can be obtained both with and without the tube. Visible reflux was detected in 27 of 30 symptomatic patients at 10-20 mm Hg, and the computed reflux index was 11.7 ± 1.8%. In 18 of 20 controls, no visible reflux was observed, while the reflux index was 2.7 ± 0.3% when pressure gradient increased to approximately 35 mm Hg. The difference in reflux indices between the two groups was significant ($p<0.001$). Changes in body position (upright versus supine) caused a decrease in reflux from 14.8 ± 3.3% to 7.6 ± 1.7% ($p<0.05$) and in LES pressure from 8.4 ± 0.08% to 6.0 ± 0.09% ($p<0.05$). An antacid-alginate preparation reduced the reflux index from 9.9 ± 1.3% to 6.5 ± 0.8% ($p<0.01$) without a significant change in LES pressure. None of the other standard diagnostic techniques (i.e., radiographic hiatal hernia, fluoroscopic reflux, LES pressure, phenol red reflux, acid perfusion, endoscopic esophagitis, and histologic esophagitis), to which the method was compared, were as sensitive. The gastroesophageal scintiscan is a reliable, noninvasive test for gastroesophageal reflux.

3022 A MULTICENTRIC, RANDOMIZED CLINICAL TRIAL OF GAVISCON IN REFLUX ESOPHAGITIS. (Eng.) McHardy, G. (Dept. Medicine, Louisiana State Univ. Medical Center, New Orleans, LA). *South. Med. J.* 71(Suppl. 1):16-21; 1978.

A multicentric evaluation of Gaviscon was performed to determine whether it is equally effective as a standard antacid in symptomatic relief of reflux esophagitis. One hundred thirty-three patients from 13 treatment centers were involved in the studies, 65 of whom received Gaviscon and 68 of whom received an antacid. Gaviscon contained 200 mg of alginic acid, 80 mg of aluminum hydroxine dried gel, 20 mg of magnesium trisilicate, and 70 mg of sodium bicarbonate per tablet. Antacid tablets were of the same physical characteristic as Gaviscon tablets and were formulated to meet the requirements of the *in vitro* test set by the Food and Drug Administration. The treatment regimens were identical in both groups. The patients were instructed to chew two tablets followed by a glass of water after each meal, at bedtime, and whenever heartburn occurred. They recorded the daily amount of medication, number and intensity of heartburn attacks, grade of relief, and the number of bowel movements. Physical examination and esophagoscopy were performed before and after the experiment. Heartburn scores, obtained by multiplying heartburn incidence by its severity, indicated no significant difference between the two treatment groups at the end of four weeks. Tablet consumption was similar in both groups. Esophagoscopy showed that Gaviscon and standard antacid were equally effective in causing a significant decrease in the severity of the specific signs of esophagitis, friability, erosion, and ulceration, as well as in such nonspecific signs as hyperemia, edema, and exudate. The low amount of antacid in Gaviscon did not cause any of the side-effects that may occur with standard antacids. Gaviscon appears to be an effective medication in the symptomatic relief of reflux esophagitis.

3023 GASTRIC EMPTYING AND ANTRAL MOTILITY IN REFLUX ESOPHAGITIS: EFFECT OF ORAL METOCLOPRAMIDE. (Eng.) Behar, J.; Ramsby, G. (Rhode Island Hosp., 593 Eddy St., Providence, RI 02902). *Gastroenterology* 74(2, Part 1):253-256; 1978.

Antral function was investigated by studying gastric emptying of the liquid phase of a meal and fasting antral contractility in 13 patients with reflux esophagitis and in 9 age-matched controls. Gastric emptying half-time ($T_{1/2}$) in reflux esophagitis patients was no different from that of control subjects ($p<0.30$). Antral contractility (number of antral contractions and the cumulative antral activity), however, was lower in reflux esophagitis patients than in control subjects ($p<0.001$). The p.o. administration of metoclopramide (15 mg) accelerated gastric emptying, increased the number of antral contractions as well as the cumulative antral activity in patients with reflux esophagitis ($p<0.001$). However, it only increased the cumulative antral activity in normal subjects ($p<0.01$). These results suggest that metoclopramide may be potentially beneficial to reflux esophagitis patients by reducing the volume of gastric contents available for gastroesophageal reflux.

3024 ANTIREFLUX SURGERY FOR SYMPTOMATIC GASTROESOPHAGEAL REFLUX: MECHANISM OF ACTION. (Eng.) Fisher, R. S.; Malmud, L. S.; Lobis, I. F.; Maier, W. P. (Temple Univ. Health Sciences Center, 3401 N. Broad St., Philadelphia, PA 19140). *Am. J. Dig. Dis.* 23(2):152-160; 1978.

To determine the effects of Nissen fundoplication upon the symptoms of reflux and on the diagnostic tests employed to evaluate reflux, and to examine the relationship between gastroesophageal reflux and lower esophageal sphincter pressure before and after fundoplication, 10 patients with symptomatic reflux were studied before and after operation. Clinical evaluation, barium esophagography, endoscopy with mucosal biopsy, esophageal manometry, acid-perfusion and acid-reflux testing, and gastroesophageal scintiscanning were performed on each patient before and after surgery. Following fundoplication, marked symptomatic, radiographic, endoscopic, and histologic improvement was observed. Serial acid-reflux tests at increasing gastroesophageal pressure gradients returned to normal after surgery. Lower esophageal sphincter (LES) pressure increased from 8.2 ± 1.3 to 12.0 ± 1.5 mm Hg ($p<0.01$). In addition, surgery resulted in a significant decrease in the gastroesophageal reflux index from 17.4 ± 2.4 to 2.7 ± 1.1% ($p<0.001$). The pre- and postoperative resting LES pressures did not correlate significantly with corresponding gastroesophageal reflux indices for individual patients. It is concluded that increased LES pressure alone does not adequately explain the functional and clinical improvement that follows fundoplication.

3042 QUANTITATION AND IMMUNOCHEMICAL CHARACTERIZATION OF CARCINOEMBRYONIC ANTIGEN AND GLUCOSE PHOSPHATE ISOMERASE IN BLOOD AND WASHINGS OF PATIENTS WITH GASTRIC AND COLONIC DISEASES. (Eng.) Munjal, D.; Brady, P. G. (Coll. Medicine, Univ. Kentucky, Lexington, KY 40506). *Am. J. Dig. Dis.* 23(1):57-64; 1978.

Carcinoembryonic antigen (CEA) and glucose phosphate isomerase (GPI) were measured in the serum and colonic washings of 51 subjects with gastric and colonic diseases to establish the usefulness of these two markers in the diagnosis of cancer. In addition, the chromatographic and immunologic properties of CEA from colonic washings were determined and compared with the characteristics of pure CEA. The levels of both markers in the serum were higher in gastric and colonic cancer patients than in normals or patients with other diseases. Elevations of both these markers were most frequent in patients with metastases; all five patients with metastases had a CEA level greater than 2.5 ng/ml, and three of the five had a simultaneously elevated GPI level. No correlation was found between total protein content and concentrations of CEA or GPI in the washings. Further characterization of the perchloric acid-soluble material from colon washings by gel filtration indicated that the CEA-like substance from colon cancer patients was higher in molecular weight than standard radiolabeled CEA or CEA from normal colon washings. When tested against anti-CEA antiserum and pure CEA from a colonic cancer metastasis, all CEA preparations showed immunological identity in gel-diffusion plates; on immunoelectrophoresis, similar mobility was indicative of a similar charge. Determination of CEA content in colonic washings is not presently a useful diagnostic tool, and the relationship between GPI in tumors and GPI in washings is still unknown and awaits isolation and characterization from both these sources.

3043 EARLY GASTRIC CARCINOMA: VALUE OF COMBINED USE OF ENDOSCOPY, AIR CONTRAST X-RAY FILMS, CYTOLOGY, AND MULTIPLE BIOPSY SPECIMENS. (Eng.) Qizilbash, A.; Harnarine, C.; Castelli, M. (Henderson General Hosp., 711 Concession St., Hamilton, Ontario L8V 1C3, Canada). *Arch. Pathol. Lab. Med.* 101(11): 610-614; 1977.

Experience with five cases of early gastric carcinoma diagnosed during a 1-yr period at one Canadian hospital is presented. All five patients were symptomatic and were diagnosed by a combination of endoscopy, roentgenology, brush cytology, and biopsy specimens. No cases of early gastric carcinoma were diagnosed at this hospital in the preceding 10 yr. Seventy-five percent of the cytological preparations were positive, and all five biopsy specimens showed carcinoma. The ulcerated or type III lesion was present in three cases. No lymph node metastases were present in the gastrectomy specimens. The increasing rate of detection of early gastric carcinoma is attributed to the use of upper gastrointestinal endoscopy, air-contrast barium meal examinations, cytology, and multiple biopsy specimens.

3044 THE RADIOLOGICAL FEATURES OF GASTRIC LYMPHOMA. (Eng.) Privett, J. T. J.; Davies, E. R.; Roylance, J. (Coventry and Warwickshire Hosp., England). *Clin. Radiol.* 28(4):457-463; 1977.

The radiological features of 18 cases of gastric lymphoma are reviewed. The appearances on barium meal were not uniform. Localized masses were seen in seven cases; four had smooth lobulated filling defects at the fundus with sharp re-entrant angles; and three had prepyloric filling defects with sharp re-entrant angles. Thickening of the mucosal folds was seen in six cases; in two cases the abnormality involved the whole stomach and extended into the duodenum, while in four cases the fundus was spared. Local pyloric rigidity was seen in four cases, and in two of these the abnormality extended into the duodenal bulb. The greatest difficulty in the diagnosis of gastric lymphoma is distinguishing it from gastric carcinoma. Even when the barium examination is obviously abnormal, the abnormality is not always recognizable as lymphoma. The following features may be used to distinguish gastric lymphoma from gastric carcinoma: distensible stomach in the presence of a mass, mucosal hypertrophy in the presence of a mass, mucosal hypertrophy associated with large gastric ulcer or multiple gastric ulcers, contiguous spread of the abnormality into the duodenal cap, duodenal ulceration associated with gastric mass, evidence of lymphoma elsewhere, and the youth of the patient (one of the 18 patients was 16 yr old; carcinoma is extremely rare at this age).

3045 β-GLUCURONIDASE AND THE GASTRIC EPITHELIAL CELL. A STUDY USING ORGAN CULTURE. (Eng.) Tayler, R.; Orwell, R. L.; Piper, D. W. (Royal North Shore Hosp., St. Leonards, New South Wales 2065, Australia). *Digestion* 16(1/2):40-47; 1977.

In vitro studies were performed to determine the significance of an increased β-glucuronidase level in the gastric juice of patients with gastric carcinoma. Gastric mucosa obtained during surgery from patients with chronic peptic ulcer or gastric carcinoma was cultured *in vitro*, and the effects of a carcinogen (N-methyl-N^1-nitro-N-nitrosoguanidine, NG) and a cytotoxic agent (nitrogen mustard) were studied. The rate of ^{14}C-glucose and ^{3}H-glycine incorporation were measured as indices of cell viability. The content of β-glucuronidase and lactic acid in the ambient fluid and LDH isoenzyme pattern of a homogenized sample of cultured tissue were the indices characterizing carcinogenic activity. The addition of NG to cultures caused an insignificant decrease in viability, while nitrogen mustard significantly decreased the viability by 90%. NG caused a significant increase in β-glucuronidase and lactate formation in the ambient fluid, regardless of the source of the gastric mucosa. When nitrogen mustard was added to the culture, β-glucuronidase and lactate production were significantly lower than in the control medium. The mean LDH M/H ratio at the end of the experiment (120 hr) was higher in the medium of tissues cultured with NG than in control medium, but the change was statistically insignificant $(0.05<p<0.1)$. The increased production of β-glucuronidase and lactate by the gastric mucosa incubated with a carcinogen suggests that the increased β-glucuronidase activity in the gastric juice of patients indicates malignancy.

3046 CYTOPLASMIC LEUCINE NAPHTHYLAMIDASE ACTIVITY EXPRESSED IN SIGNET-RING CELL CARCINOMA OF THE STOMACH. (Eng.) Kubota, K.; Yamada, S.; Ito, M.; Nakamura, W.; Nagayo, T. (Aichi Cancer Center, Tashiro-cho, Kanokoden, Chikusa-ku, Nagoya 464, Japan). *J. Natl. Cancer Inst.* 59(6):1599-1604; 1977.

Histochemical studies were carried out in signet-ring cells in surgically resected gastric carcinomas from 64 patients. On the basis of PAS reactivity of the intracellular mucin, the signet-ring cells were classified as type A (immature), type B (intermediate), or type C (mature). Different staining reactions to Alcian blue at pH 2.5 enabled type C cells to be subclassified as C-1 or C-2. In 63/64 cases, intense leucine naphthylamidase (LNAase) activity was found in the cytoplasm of nearly all cancer cells except type C-2. Localization of LNAase activity in the cytoplasm was confirmed by conventional biochemical assay. These findings do not support the classification of the signet-ring carcinoma as a poorly differentiated adenocarcinoma. The authors believe that the signet-ring carcinoma is a cancer with some functions attributable to its cellular characteristics.

3047 GASTRIC DEVASCULARIZATION: A USEFUL SALVAGE PROCEDURE FOR MASSIVE HEMORRHAGIC GASTRITIS. (Eng.) Richardson, J. D.; Aust, J. B.

In: Transactions of the Southern Surgical Association Eighty-Eighth Annual Meeting Held at the Breakers Palm Beach, Florida, December 6, 7, 8, 1976. (Philadelphia: J. B. Lippencott Co.): 88: 157-163; 1977.

Due to poor results with conventional operative therapy for diffuse hemorrhagic gastritis (DHG), a prospective evaluation of gastric devascularization was carried out in 21 patients. Sepsis, alcoholism, and steroid abuse were the common etiologic factors. Eighteen patients had previously undergone vagotomy and pyloroplasty, and 19 patients had undergone gastric resection. In spite of the fact that these were all critically ill patients, all stopped bleeding with gastrin devascularization, and only two rebled. The average operating time was 84 min. There were two operative complications, and gastric necrosis did not occur. The mortality was high (38%) due to the primary disease. Gastric devascularization is a useful salvage procedure for the patient with DHG because it can be accomplished rapidly, with few complications, has a low rebleed rate, and causes no permanent sequelae. Gastric devascularization is in many ways the ultimate ischemic preparation for the gastric mucosa, which attests to the poor understanding of this complex disease, since only 2/21 patients rebled.

3048 BILE ACID COMPOSITION IN PATIENTS WITH AND WITHOUT SYMPTOMS OF POSTOPERATIVE REFLUX GASTRITIS. (Eng.) Gadacz, T. R.; Zuidema, G. D. (Veterans Admin. Hosp., 3900 Loch Raven Blvd., Baltimore, MD 21218). *Am. J. Surg.* 135(1):48-52; 1978.

Gastric aspirates from symptomatic and asymptomatic patients with bile reflux after operation for duodenal ulcer were quantitatively and qualitatively analyzed to determine if there is a relation between bile acid concentrations and symptoms of bile reflux after surgery. Four patients were asymptomatic, and the bile composition was normal. Three patients were symptomatic and had a significant increase in secondary bile acids (36.3% of total bile acids, compared with 13.2% in asymptomatic patients, $p<0.05$), which was accounted for by an increase in deoxycholic acid. The concentration of bile acid was similar in the two groups. This alteration in bile acid composition, with an increase in deoxycholic acid, may be an important factor in determining which patients with bile reflux develop gastritis.

3049 SIMULTANEOUS MANIFESTATION OF MENETRIER'S DISEASE. SUPERFICIAL ULCERATION (DIEULAFOY'S DISEASE) AND EARLY GASTRIC CANCER (A CASE REPORT). (Ger.) Stosiek, P.; Ebermann, W.; Varga, A. (Bezirkskrankenhaus, Girbigsdorfer Str. 1/3, DDR-89 Gorlitz, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 37(5/6):247-253; 1977.

Acute gastric hemorrhage prompted gastric resection in a 51-yr-old man with uneventful familial and personal anamnesis. Type IIb early gastric cancer, superficial ulceration (Dieulafoy's disease), and morphological changes typical of Menetrier's disease were found in the surgical specimen. The patient was discharged in good condition 5 weeks after surgery. Alpha-1-antitrypsin was found in the feces 1 yr after surgery. The combination of these three diseases has not been described before in the literature. Superficial erosion is not uncommon in Menetrier's disease. Many case reports and epidemiological studies show a relationship between Menetrier's disease and early gastric cancer.

3050 RECURRENCE RISKS IN COMPLEX INHERITANCE WITH SPECIAL REGARD TO PYLORIC STENOSIS. (Eng.) Lalouel, J. M.; Morton, N. E.; MacLean, C. J.; Jackson, J. (Population Genetics Lab., Univ. Hawaii at Manoa, 1980 East-West Rd., Honolulu, HI 96822). *J. Med. Genet.* 14(6):408-414; 1977.

A mixed model was applied to a body of data on pyloric stenosis to determine recurrence risks, whose incidence varies with sex, birth order, and ethnic group. Data for this analysis were drawn from three previously published studies of familial incidence of pyloric stenosis performed in Great Britain. The mixed model postulates an underlying scale of liability, to which a major locus, a polygenic component, and environment contribute independently. The major locus is assumed to be biallelic, producing three genotypes. The polygenic and environmental factors are assumed to be independent and normally distributed. Population incidences of pyloric stenosis were the input data in segregation analysis. Probability of ascertainment was established separately for each subsample because of heterogeneity among the subsamples. The hypothesis of the mixed model, the generalized single locus model, and the multifactorial model were employed in the segregation analysis. Recurrence risks of pyloric stenosis for various family histories can be computed with the program RISK, which is described. Examples were given to illustrate how risks vary with family history. It is concluded that in the majority of cases of pyloric stenosis, the method of computing the recurrence risks on the basis of the mixed model is adequate and reliable.

3051 GASTRIC EPITHELIAL CELL TURNOVER, MUCUS PRODUCTION, AND HEALING OF GASTRIC ULCERS WITH CARBENOXOLONE. (Eng.) Domschke, W.; Domschke, S.; Hagel, J.; Demling, L.; Croft, D. N. (Dept. Medicine, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Gut* 18(10):817-820; 1977.

The effects of carbenoxolone on proliferation and mucus production were studied in 17 patients with gastric ulcer before and after ulcer healing with carbenoxolone treatment and in 19 healthy subjects. Gastric DNA loss was measured as an index of epithelial cell turnover, and *N*-acetylneuraminic acid (NANA) content of gastric juice as an index of mucus secretion. In normal subjects there was a negative correlation ($p<0.025$) between gastric DNA loss and NANA secretion: the lower the cell turnover, the higher the NANA production. In gastric ulcer patients, DNA loss or turnover was significantly ($p<0.01$) higher than normal, and fell significantly ($p<0.01$) after 4 weeks of treatment with carbenoxolone, when 16 of the 17 ulcers had healed. At the same time, NANA output increased significantly ($p<0.01$). It is suggested that patients with gastric ulcer lose cells at a high rate that is returned to normal by carbenoxolone, thus allowing the epithelial cells to mature within the mucosa and produce more mucus.

3052 FIRST CLINICAL EXPERIENCES WITH CHOLESTYRAMINE FOR THE PROPHYLAXIS OF STRESS ULCER.

(Ger.) Schumpelick, V.; Grossner, D. (Chirurgischen Universitatsklinik und -Poliklinik, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Munch. Med. Wochenschr.* 119(41):1329-1332; 1977.

Sixty-eight patients at risk of stress ulcer were treated prophylactically with cholestyramine (2 g/2 hr in 20 ml water) with a probang and/or an antacid (Gelusil Lac). Polytrauma with or without involvement of the skull and brain, surgical intervention, burn, reanimation, and sepsis were the indications of the prophylactic treatment. Forty-four patients received cholestyramine, including eight patients who also received antacid. Twenty-four patients received antacid only. None of the 44 cholestyramine-treated patients developed stress ulcer, but one patient, who received cholestyramine without antacid, had bleeding from an erosion that was controlled conservatively. Two of the 24 antacid-treated patients developed bleeding stress ulcers; 1 of them died from the indirect sequelae of the hemorrhage. No side-effects of treatment were observed. The findings indicate the effectiveness of cholestyramine in the prophylaxis of stress ulcer. The elimination of the ulcerogenic function of the duodenogastric reflux is discussed as the possible mode of action of cholestyramine.

3053 GASTRIC ULCER: EFFECT OF HEALING ON GASTRIC ACID SECRETION AND FASTING SERUM GASTRIN LEVELS.

(Eng.) Boyle, J. M.; Hurwitz, A. L.; Jones, R. S.; Mansbach, C. M., II (Univ. Hosp. Cleveland, Cleveland, OH 44106). *Am. J. Dig. Dis.* 22(12):1037-1039; 1977.

To determine whether the normal or low gastric acid output observed during active gastric ulceration is an intrinsic property of the gastric mucosa or if acid output is lowered by factors that precipitate the active ulceration, basal and peak gastric acid outputs and fasting serum gastrin levels were studied before and after healing in 15 patients with uncomplicated benign gastric ulcers. The mean basal acid output (4.0 ± 1.3 mEq H^+/hr), the mean peak acid output (29.5 ± 5.1 mEq H^+/hr), and the mean fasting serum gastrin level (80.3 ± 16.7 pg/ml) in these patients did not change significantly with healing. Failure of gastric secretory function to change with healing suggests that mucosal resistance factors are more important than gastric acid secretion in the pathogenesis of a gastric cancer.

3054 GASTRIC ULCERATION IN PATIENTS RECEIVING INTRAHEPATIC INFUSION OF 5-FLUOROURACIL.

(Eng.) Narsete, T.; Ansfield, F.; Wirtanen, G.; Ramirez, G.; Wolberg, W.; Jarrett, F. (Univ. Wisconsin Center for Health Sciences, Madison, WI). *Ann. Surg.* 186(6):734-736; 1977.

The cases of 8 patients who developed gastric ulcer, and were among 251 receiving intrahepatic arterial infusion chemotherapy for hepatic metastases, were reviewed. All patients received 5-fluorouracil (5-FU, 20-30 mg/kg for 4 days, followed by 15 mg/kg for 17 days). Bleeding occurred in four of the eight ulcer patients and perforation in one. In all cases, the catheter tip had been dislodged and was proximal to its correct position, allowing the stomach to be directly infused with 5-FU. No duodenal ulcers were noted. All patients were symptomatic for several days before the diagnosis was made. Of 20 patients with catheter dislodgement, 5 had documented ulcers, 3 had upper gastrointestinal bleeding of undetermined etiology, 8 had epigastric pain or vomiting, and only 4 were asymptomatic. Prompt determination of catheter position is necessary in patients receiving intrahepatic arterial infusion of 5-FU if symptoms consistent with gastric ulceration occur. Gastric ulcers should be vigorously treated because of the high rate of complications in patients receiving chemotherapy.

3055 ACUTE MULTIPLE GASTRIC ULCERS IN THE PYLORIC ANTRUM.

(Eng.) Yoshida, T.; Kubo, H.; Murata, H.; Ando, K.; Ishii, H.; Miyagi, F. (Saitama Medical Coll., 38 Morohongo, Moroyama, Jruma-Gun, Saitama-Ken, Japan). *Endoscopy* 9(4): 223-228; 1977.

Clinical studies on the causes and development of acute multiple gastric ulcers were performed on outpatients who suffered from fulminant epigastralgia, vomiting, and nausea. Endoscopic examination of these patients was made every few days. The ulcer presented in four clinical stages. During a preparatory (resting) period (stage 1) several minor hemorrhagic erosions in the upper part of the gastric body were found, but no abnormalities in the pyloric antrum were observed. In 25 patients (89%) who continued excessive use of liquors and food or coffee, nausea and vomiting with abrupt epigastralgia occurred, and 3 patients (10%) had hematemesis and melena. Endoscopy showed hemorrhagic erosions surrounding the pyloric sphincter. It was defined as an early ulcer stage 2. Two to five days later, the hemorrhagic erosions subsided, but symmetrical linear ulcers appeared on the pyloric sphincter, occasionally accompanied by one or two ulcers above the gastric angle (stage 3). After seven weeks of treatment, a stage of scarred healing was observed (stage 4). The disease occurred most frequently in juvenile and middle-aged patients. Its incidence increased in spring and summer. Gastric biopsies demonstrated cytomegalic inclusion bodies (CMIB). Hyperchlorhydria was found in 89% of the patients during the acute phase of the disease, but it decreased spontaneously with time. It is suggested that a virus may invade the mucosa, and CMIB obstructs the capillary endothelium, which causes erosions. Excessive ingestion of food, liquors, or coffee leads to the multiple gastric ulcers.

3056 AN ELECTRON MICROSCOPIC STUDY OF THE CILIATED CELLS IN THE HUMAN GASTRIC MUCOSA. (Eng.) Okuda, T.; Ogata, T. (Okayama Univ. Medical Sch., Okayama, 700 Japan). *Arch. Histol. Jpn.* 39(3):149-156; 1976.

The cytological features of ciliated cells found in the mucosa of the human stomach in three patients are described. In two cases, they occurred in the pyloric mucosa of patients with intestinal metaplasia who were operated on for duodenal ulcer. In the other case, they occurred within a polypoid lesion. They were located in small limited areas. The cells were densely ciliated, each cilium showing a typical 9 + 2 fibrilar pattern. Ciliated cells are not found in normal gastric mucosa, suggesting that they occur only in pathologically altered mucosa.

3057 KREBS CYCLE, PENTOSE PHOSPHATE PATHWAY, AND GLYCOLYSIS IN THE UNINVOLVED GASTRIC MUCOSA OF PEPTIC ULCER AND GASTRIC CANCER PATIENTS. (Eng.) Orwell, R. L.; Piper, D. W. (Royal North Shore Hosp. Sydney, St. Leonards, New South Wales 2065, Australia). *Gastroenterology* 73(6):1320-1325; 1977.

The body and antral mucosa of chronic peptic ulcer patients, together with the body mucosa, antral mucosa, and tumor tissue of gastric cancer patients, were compared in *in vitro* experiments as regards rates of glucose utilization, the relative contributions to glucose metabolism of the pentose phosphate pathway and Krebs cycle, and the rates of glycolysis within the tissues. $[^{14}C]$glucose counts retained by the tissue, glycolysis, and pyruvate formation were also measured. Tumor tissue from the cancer patients was included in the study. Less than 1.2% of the glucose entering the tissues was metabolized via the pentose phosphate pathway, suggesting that this pathway plays a minor role in energy production from glucose. The major determinant of energy production was the Krebs cycle. Its contribution to glucose metabolism was greatest in the body mucosa of duodenal ulcer patients, less in the uninvolved body mucosa of gastric ulcer patients, and lower still in the corresponding body mucosa of gastric cancer patients. The low levels of Krebs cycle activity seen in the latter tissue resembled those of uninvolved antral mucosa. The smallest Krebs cycle contribution was seen in tumor tissue. $[^{14}C]$glucose counts retained by the tissue and glycolysis both tended to vary inversely with Krebs cycle activity among the tissues studied. Thus, both were small in the body mucosa of noncancer patients and somewhat larger in the body mucosa of cancer patients, in uninvolved antral mucosa, and in tumor tissue.

3058 REFLUX CONTROL FOLLOWING GASTROPLASTY. (Eng.) Henderson, R. D. (Women's Medical Coll. Hosp., 76 Grenville St., Toronto, Ontario M58 1B2, Canada). *Ann. Thorac. Surg.* 24(3):206-214; 1977.

STOMACH

Peptic Ulcers

3094 DYNAMIC ASPECTS OF GASTRIC EMPTYING IN PATIENTS WITH PEPTIC ULCER ACCORDING TO ULCER STAGES. (Eng.) Miyaoka, T.; Misaki, F.; Sasaki, Z.; Kimoto, K.; Kawai, K. (Kyoto Prefectural Univ. Medicine, Kawaramachi-Hirokoji, Kamigyo-ku, Kyoto, 602, Japan). *Digestion* 16(1/2):10-17; 1977.

To analyze the pattern of gastric emptying and to clarify the difference in the rate of emptying according to the site of peptic ulcer, the pattern and the time of gastric emptying were investigated in 38 patients with peptic ulcer and 7 healthy volunteers using the double-sampling method. The pattern of gastric emptying was exponential in 44% of the cases, quadratic in 29%, and unclassified in 27%. These patterns appeared to depend on the distance from the gastric angle to the pyloric ring measured from x-ray pictures in the upright position. There was no significant difference in the gastric emptying time in patients with peptic ulcer according to its site. During follow-up observations of the same case, the gastric emptying time had a tendency to shorten in patients with duodenal ulcer, while it showed no definite variation in patients with gastric ulcer.

3095 G-CELL COUNTS IN ANTRAL ENDOSCOPIC BIOPSIES BY IMMUNOFLUORESCENCE. (Eng.) Crivelli, O.; Pera, A.; Ferrari, A.; Rizzetto, M.; Lombardo, L.; Babando, G.; *et al.* (Ospedale Mauriziano Umberto I--Corso Turati 46, 10128 Torino, Italy). *Scand. J. Gastroenterol.* 12(6):721-726; 1977.

Antral gastrin-producing cells (G cells) were counted by an immunofluorescence technique in the antral biopsies obtained at endoscopy from 18 patients with duodenal ulcer, 17 patients with gastritis, and 32 individuals with a normal gastric mucosa. The G-cell count was significantly lower ($p<0.01$) in patients with duodenal ulcer (142 G cells/mm^2) in comparison to normal subjects (327 G cells/mm^2). No statistically significant correlation was found between the G-cell number and any of the other parameters tested (pentagastrin test, basal serum gastrin, and its response to a standard meal). The G-cell count could be relevant in the preoperative assessment of the G-cell density in duodenal ulcer patients.

3096 ACUTE PEPTIC ULCER IN INFANCY AND CHILDHOOD. (Eng.) Grosfeld, J. L.; Shipley, F.; Fitzgerald, J. F.; Ballantine, T. V. (Indiana Univ. Sch. Medicine, Indianapolis, IN). *Am. Surg.* 44(1):13-19; 1978.

Acute peptic ulcers were studied in 29 infants and children (15 girls and 14 boys; ages 1 day to 18 yr, mean=7.2 yr). The ulcer was a solitary lesion in all but one case, occurred equally in the duodenum (15) and stomach (14), and was associated with a 14% mortality rate. Location of the ulcer was unrelated to sex and age. Associated factors observed were "ulcerogenic" medications in 12 patients (aspirin, 7; steriods, 4; lomotil, 1), postoperative condition (following ruptured appendix in 2 and Tetralogy of Fallot in 1), burns (2), hepatic coma (1), psoriasis (1), and respiratory insufficiency (1). Diagnostically, endoscopy was the most useful procedure, with angiography and upper gastrointestinal contrast studies useful in selected cases. Treatment by ligation, vagotomy, and pyloroplasty elicited good responses in complicated cases resulting in hemorrhage. Lesser operations occasionally resulted in recurrence. Preventative measures, including postoperative and post-trauma antacid therapy in high-risk patients, are recommended, as they are preferable to any treatment course.

3097 TREATMENT OF PEPTIC ULCER DISEASE IN THE RENAL TRANSPLANT PATIENT. (Eng.) Owens, M. L.; Passaro, E., Jr.; Wilson, S. E.; Gordon, H. E. (Veterans Admin. Wadsworth Hosp. Center, Wilshire and Sawtelle Blvd., Los Angeles, CA). *Ann. Surg.* 186(1):17-21; 1977.

Previous reports of peptic ulcer disease in kidney transplant recipients are reviewed. In addition, the authors' experience with 21 cases, occurring in 115 renal transplant patients, is presented. Between 1968 and 1976, 12 transplant centers reported on gastrointestinal complications occurring in 1,853 renal transplant recipients. Among these are 52 patients in whom peptic ulcers developed before transplantation and 72 patients in whom peptic ulcers developed after transplantation. Patients who were operated on for peptic ulcer before transplant were compared with patients with peptic ulcer before transplant but who were not operated on. Ulcer recurrence was significantly lower in the operated group ($p<0.0003$). Following transplantation, 59 of 68 patients with peptic ulcer disease presented with bleeding or perforation. There were 31 deaths in 72 patients. Symptoms usually occurred early, 74% in 6 months, but 19% occurred after 1 yr. The mortality from duodenal, gastric, combined gastric and duodenal, and recurrent ulcers did not differ significantly. Elective surgery is indicated for peptic ulcer when demonstrated before or after kidney transplantation.

3098 EVALUATION OF CARBENOXOLONE SODIUM IN THE TREATMENT OF DUODENAL ULCER. (Eng.) Nagy, G. S. (14 Marshall Ave., St. Leonards, New South Wales, Australia). *Gastroenterology* 74(1):7-10; 1978.

The healing of duodenal ulcers over a 6-week period was assessed endoscopically in a double blind trial involving 21 patients on carbenoxolone and 23 patients on placebo. The two groups were adequately matched, with the exception that larger ulcers predominated in the carbenoxolone group (there were 15 patients with ulcers >1 cm in the carbenoxolone group, versus 9 in the placebo group). Relief of symptoms showed poor correlation with ulcer healing. Fourteen of the 21 patients in the carbenoxolone group and 7 of the 23 in the placebo group showed endoscopic evidence of complete healing. The result is highly significant ($p<0.016$) and confirms the therapeutic efficacy of carbenoxolone sodium positioned-release capsules in the treatment of duodenal ulcers. Side-effects of carbenoxolone therapy in the form of weight gain, rise in diastolic blood pressure, and hypokalemia were observed, but with adequate monitoring and appropriate countermeasures, no patient suffered any ill effects.

3099 ULTRASTRUCTURE OF DUODENAL EPITHELIAL CELLS IN PATIENTS WITH ACTIVE DUODENAL ULCERS AND AFTER TREATMENT WITH CIMETIDINE. (Eng.) Pillay, C. V.; Moshal, M. G.; Bryer, J. V.; Booyens, J. (Dept. Physiology, Univ. Durban-Westville, Durban, South Africa). *S. Afr. Med. J.* 52(27):1082-1085; 1977.

Comparative ultrastructural studies were carried out in biopsy specimens taken under direct vision by endoscopy from the normal duodenum, from the edge of deep and flat duodenal ulcers, and from areas 1 cm away from such ulcers. In addition, the ultrastructure of biopsy tissue from the scar of ulcers that healed after 6 weeks' therapy with cimetidine was studied. Tissue from the edge of both flat and deep duodenal ulcers showed gross pathological changes, particularly with regard to microvilli. Cells from the edge of deep ulcers showed increased secretory activity. Epithelial tissue 1 cm from flat duodenal ulcers exhibited ultrastructural changes more severe than cells 1 cm from deep duodenal ulcers. The epithelial tissue from the scar area after 6 weeks' treatment appeared capable of regaining a fully functional role, although it was abnormal (irregularly shaped microvilli) in some specimens.

3100 EFFECT OF LOW-DOSE PROPANTHELINE ON FOOD-STIMULATED GASTRIC ACID SECRETION: COM-

PARISON WITH AN "OPTIMAL EFFECTIVE DOSE" AND INTERACTION WITH CIMETIDINE. (Eng.) Feldman, M.; Richardson, C. T.; Peterson, W. L.; Walsh, J. H.; Fordtran, J. S. (Veterans Admin. Hosp., 4500 S. Lancaster Rd., Dallas, TX 75216). *N. Engl. J. Med.* 297 (26):1427-1430; 1977.

The widely held notion that anticholinergic drugs must be used in near toxic doses to inhibit gastric acid secretion effectively was re-examined, and the effect of a small dose of an anticholinergic on the inhibitory effect of an H_2-receptor antagonist was investigated. Nine patients with duodenal ulcer were studied after a low dose (15 mg) and after a near toxic dose (averaging 48 mg) of propantheline. The mean inhibition of food-stimulated acid secretion was identical with the two doses of propantheline (29 ± 10 and 29 ± 11%, resp). In addition, when 15 mg of propantheline were combined with cimetidine (300 mg), acid secretion was suppressed to a greater degree than with either drug alone. A low dose of propantheline is as effective as a near toxic dose in suppressing food-stimulated acid secretion and augments the inhibitory effect of cimetidine.

3101 EVALUATION OF DUOGASTROME (CARBENOXOLONE SODIUM) FOR THE TREATMENT OF DUODENAL ULCER: A MULTICENTRE STUDY.

(Eng.) Archambault, A.; Farley, A.; Gosselin, D.; Martin, F.; Birkett, J. P. (Centre de gastro-enterologie de Montreal, 235, est Dorchester, Ste 101, Montreal, Quebec H2X 1N8, Canada). *Can. Med. Assoc. J.* 117(10): 1155-1159; 1977.

A double-blind study of the effectiveness of carbenoxolone sodium was carried out in 152 duodenal ulcer patients. Seventy-six patients received carbenoxolone sodium capsules (50 mg, q.i.d.), and 76 received placebo capsules (q.i.d.) for 6 weeks. Evaluation of the efficacy of carbenoxolone therapy was based on data from 119/152 patients (59 test subjects and 60 controls). The ulcers healed completely (as assessed by either endoscopy or roentgenography) in 44/59 of the patients treated with carbenoxolone and in 29/60 of those treated with placebo ($p<0.01$). The proportions were similar if only endoscopical assessments are considered: 32/42 and 26/47, resp. Minor side-effects (weight gain, edema, mild hypokalemia, increase in blood pressure, and slight increases in serum concentrations of lactic dehydrogenase and alkaline phosphatase) were noted in the carbenoxolone-treated patients. Although these side-effects were not serious, close clinical monitoring by weekly visits to their physician is recommended for every patient undergoing carbenoxolone therapy, at least during the first month.

3102 EFFECT OF SOMATOSTATIN ON MEAL-INDUCED GASTRIC SECRETION IN DUODENAL ULCER PATIENTS.

(Eng.) Konturek, S. J.; Swierczek, J.; Kwiecien, N.; Mikos, E.; Oleksy, J.; Wierzbicki, Z. (Inst. Physiology, 16 Grzegorzecka St., 31-531 Krakow, Poland). *Am. J. Dig. Dis.* 22(11):981-988; 1977.

The effect of somatostatin (GH-RIH) on basal and meal-, pentagastrin-, or histamine-stimulated gastric acid and pepsin secretion was studied in six duodenal ulcer patients. Pentagastrin and histamine were infused i.v. at 2 and 25 μg/kg/hr, resp. The i.v. infusion of GH-RIH in graded doses ranging from 0.62 to 5.0 μg/kg/hr produced a dose-related inhibition of pentagastrin-induced acid secretion, reaching about 15% of control level at the dose of 5.0 μg/kg/hr. Acid inhibition was paralleled by a decrease in the pepsin output and accompanied by a dose-dependent reduction in serum growth hormone and insulin levels measured by radioimmunoassay. GH-RIH used in a single dose of 2.5 μg/kg/hr produced about 85% inhibition of acid secretion induced by a meal (measured by intragastric titration) accompanied by a significant decrease in serum gastrin and insulin levels. The effect of GH-RIH on histamine-stimulated secretion was very modest and observed only after stopping the GH-RIH infusion. Thus, GH-RIH suppresses acid and pepsin secretion induced by pentagastrin and a meal, and this effect is accompanied by a suppression of serum growth hormone and gastrin levels, which may contribute to the observed inhibition of gastric secretion.

3103 INHIBITION OF GASTRIN SECRETION BY SULPIRIDE TREATMENT IN DUODENAL ULCER PATIENTS.

(Eng.) Caldara, R.; Romussi, M.; Ferrari, C. (Fatebenefratelli Hosp., 23 Corso di Porta Nuova, 20121 Milano, Italy). *Gastroenterology* 74(2, Part 1): 221-223; 1978.

The serum gastrin response to whole beef extract was measured in 14 duodenal ulcer patients before and after sulpiride administration (100 mg). A significant inhibition of response was found both after acute i.m. injection of the drug and after p.o. administration for 1 week (100 mg/8 hr). Fasting serum gastrin was also significantly reduced after chronic treatment; gastric acid secretion did not change. Although the mechanism of the gastrin-lowering action of sulpiride is unknown, it could be mediated by some known effect(s) of the drug, such as modifications in brain monoamine metabolism or perhaps reduced growth hormone secretion.

3104 EFFECT OF VARIOUS PYLOROPLASTIES ON FECAL FAT EXCRETION IN DOGS AND HUMANS.

(Eng.) Wastell, C.; Ellis, H. (Westminster Hosp., St. Johns Gardens, London SW1P 2AP, England). *Am. J. Dig. Dis.* 23(1):45-50; 1978.

Fecal fat excretion was measured both before and after truncal vagotomy and pyloroplasty in 25 patients with chronic duodenal ulcer and in dogs before and after pyloroplasty alone. In 13 patients, the mean increase in fecal fat after truncal vagotomy and Heineke-Mikulicz pyloroplasty was 2.34 g/24 hr. After truncal vagotomy and Finney pyloroplasty in 12 patients, the increase was similar (3.09 g/24 hr). Fecal fat was also measured before and after a 3-cm, a 6-cm Heineke-Mikulicz, and a Finney type of pyloroplasty in dogs. The area resulting from the pyloroplasties was measured. Pyloroplasty resulted in a significant increase in fecal fat ($0.02<p<0.05$), but no correlation was found between the magnitude of the increase and the area that resulted from the pyloroplasties. It is concluded that, when considering which type of pyloroplasty to use after either truncal or selective vagotomy, the most important considerations are technical and relate to satisfactory drainage of the antrum.

3105 INTRINSIC FACTOR SECRETION AFTER VAGOTOMY. (Eng.) Meikle, D. D.; Bull, J.; Callender, S. T.; Truelove, S. C. (West Middlesex Hosp., Isleworth, Middlesex, England). *Br. J. Surg.* 64 (11):795-797; 1977.

To compare the effects of truncal vagotomy with highly selective vagotomy on the histological state of the gastric and duodenal mucosa, and or serum gastrin, the intrinsic factor (IF) output during basal and Histalog-stimulated gastric secretion was estimated in two series of patients with chronic duodenal ulcer before and 3 months or more after treatment by either highly selective vagotomy or truncal vagotomy and pyloroplasty. Each procedure produced significant reductions in intrinsic factor secretion after Histalog stimulation ($p<0.001$). This confirms the view expressed by previous workers that it is the vagotomy as such that is responsible for this effect, excluding the drainage procedure from any possible role. Both types of vagotomy again produced a significant reduction in IF secretion when measured 3 months or more after surgery, suggesting that the depressed IF secretion is a permanent feature and one that is postulated to become progressively more severe. In both series there was a marked reduction in IF output during the second hour of stimulated gastric secretion, indicating an early wash-out of preformed IF. This finding persisted after vagotomy.

3106 SUBGROUPS OF PEPTIC ULCER PATIENTS. (Eng.) Eckensberger, D.; Overbeck, G.; Biebl, W. (Zentrum fur Psychosomatische Medizin an der Universitat Giessen Abt. Medizinische Soziologie, Ludwigstr. 50, 6300 Giessen, W. Germany). *J. Psychosom. Res.* 20(5):485-499; 1976.

SMALL INTESTINE

3136 ALPHA HEAVY-CHAIN DISEASE IN SOUTHERN IRAN. (Eng.) Haghshenass, M.; Haghighi, P.; Abadi, P.; Kharazmi, A.; Gerami, C.; Nasr, K. (Pahlavi Univ. Sch. Medicine, Shiraz, Iran). *Am. J. Dig. Dis.* 22(10):866-873; 1977.

A prospective study of 32 patients in Southern Iran with primary upper small intestinal lymphoma revealed 10 cases of alpha heavy-chain disease. Patients were mostly in the second and third decades of life, and the male-female ratio was 4:1. Weight loss, diarrhea, and abdominal pain were the most common complaints, and clubbing was the most frequent physical finding. Laboratory tests revealed a malabsorption pattern on intestinal x-rays, and malabsorption of xylose, fat, and vitamin B_{12} was frequently noted. Dense plasmacytic infiltrate of the lamina propria of the small bowel was the most frequent pathologic finding, while true neoplasm of the lymphoid system (i.e., immunoblastic sarcoma) was encountered in 20% of the cases.

3137 PRODUCTION OF VITAMIN B12 ANALOGUES IN PATIENTS WITH SMALL-BOWEL BACTERIAL OVERGROWTH. (Eng.) Brandt, L. J.; Bernstein, L. H.; Wagle, A. (Montefiore Hosp. and Medical Center, 111 East 210th St., Bronx, NY 10467). *Ann. Intern. Med.* 87(5):546-551; 1977.

The presence of vitamin B12 analogues (cobamides) and the bacterial conversion of ^{57}Co-B12 (vitamin B12 cyanocobalamin, [^{57}Co]CN-Cbl) into cobamides in the intestinal contents were investigated in four patients with bacterial overgrowth. The (^{57}Co)-CN-Cbl bound to intrinsic factor was given p.o. Jejunal contents were aspirated for 24 hr and cultured aerobically and anaerobically. The CN-Cbl and cobamides were separated by electrophoresis and chromatography and identified by bioautography. Radioactivity of cobamide zones from duplicate chromatograms showed bacterial conversion of (^{57}Co)-CN-Cbl into cobamides. Cobamides ([Ade]CNCba, [2-Me Ade]CNCba, [CN]$_2$Cbi, and factor E) were found in the intestinal contents in three of the four patients, and in two of three patients cobamides represented more than 25% of the administered CN-Cbl. Thus, bacterial production of cobamides, both *de novo* and from ingested CN-Cbl bound to intrinsic factor, occurs in humans with bacterial overgrowth and results in a significant loss of vitamin B12 to the host.

3138 THE CONSEQUENCES OF SMALL INTESTINAL RESECTION. (Eng.) Compston, J. E.; Creamer, B. (St. Thomas' Hosp., London, SE1, England). *Q. J. Med.* 46(184):485-497; 1977.

Forty-three patients who underwent resection of part of the small intestine were followed at a combined medical and surgical outpatient clinic. Thirty-eight patients had Crohn's disease, and in 11 patients the disease was active at the time of the study. The length of small intestine resected was 15-194 cm in the 30 patients in which this was documented. Some colon had also been resected in 41 patients. Codeine phosphate or Lomotil (diphenoxylate hydrochloride plus atropine) and dietary fat restriction were effective in controlling diarrhea in most patients, although none reached the desired target of 40 g of fat a day. Approximately half of the patients were at or above their ideal weight. Patients with active disease required more drug therapy than those without, but otherwise they were very similar. The mean hemoglobin and serum albumin levels were normal and did not differ significantly from those without active disease. Only five patients were unable to work full-time because of illness. Six patients had histological evidence of osteomalacia, one developed night blindness due to vitamin A deficiency, and vitamin K deficiency developed suddenly in one other patient. Megaloblastic anemia due to folic acid deficiency occurred in one patient who had undergone jejunal resection. It is concluded that the prognosis of patients following small bowel resection is good, even when resection has been extensive and active disease remains, provided that specific deficiencies are promptly diagnosed and treated. The length of small intestine remaining after resection seems to be unimportant in determining prognosis.

3139 OSTEOMALACIA AFTER SMALL-INTESTINAL RESECTION. (Eng.) Compston, J. E.; Ayers, A. B.; Horton, L. W. L.; Tighe, J. R.; Creamer, B. (St. Thomas' Hosp., London, SE1, England). *Lancet* 1(8054):9-12; 1978.

The prevalence of histological osteomalacia and its relationship to clinical, biochemical, and radiological variables was studied in 25 patients with small intestinal resection, and the response of 4 patients to vitamin D therapy was examined. Nine patients had osteomalacia, which was severe in five and mild in four. The serum alkaline phosphatase concentration was raised in all patients with severe osteomalacia, but serum calcium, phosphate, and alkaline phosphatase concentrations were normal in the four patients with mild disease, two of whom had symptoms. Osteomalacia was diagnosed radiologically in only three patients. Osteomalacia appears to be more common in patients with small intestinal resection than has previously been thought, and bone biopsy is essential if all cases are to be detected. High-dose parenteral (i.m.) vitamin D therapy was successful in two of three patients treated for 1 yr. The remaining patient and another patient were treated with p.o. 1α-hydroxyvitamin D_3; bone histology and biochemistry returned to normal after 6 months in both cases.

3140 SUCCESSFUL REVASCULARIZATION OF MESENTERIC INFARCTION FOLLOWING AORTOGRAPHY. (Eng.) Sumner, D. S. (St. John's Hosp., Room 292, Springfield, IL 62702). *Ann. Surg.* 43(11):743-750; 1977.

Two cases of bowel infarction following abdominal aortography are presented. In both patients, a 57-yr-old man and a 47-yr-old woman, two of the three major arteries supplying the bowel were occluded before the study. The superior mesenteric artery in one and the inferior mesenteric artery in the other were the only arteries supplying the bowel, and their lumens were reduced. After the aortogram, the residual lumen clotted, leading to bowel necrosis. Both patients survived following revascularization of the superior mesenteric artery and necrotic bowel resection.

3141 "MEDITERRANEAN ABDOMINAL LYMPHOMA," OR IMMUNOPROLIFERATIVE SMALL INTESTINAL DISEASE. PART I: CLINICAL ASPECTS. (Eng.) Salem, P. A.; Nassar, V. H.; Shahid, M. J.; Hajj, A. A.; Alami, S. Y.; Balikian, J. B.; *et al.* (American Univ. Beirut Hosp., Beirut, Lebanon). *Cancer* 40(6):2941-2947; 1977.

Twenty-five cases in one hospital of "Mediterranean abdominal lymphoma," better known as immunoproliferative small intestinal disease (IPSID) are reported. All patients were Moslem Arabs from low socioeconomic background. The mean age was 25 yr. IPSID was shown to be a distinct disease entity characterized by a triad of clinical, pathological, and immunoglobulin abnormalities. The clinical manifestations of the disease included chronic diarrhea, weight loss, diffuse abdominal pain, finger and toe clubbing, and occasionally palpable peripheral lymph nodes. Radiological studies revealed a malabsorption pattern with evidence of mucosal fold thickening, segmentation, and flocculation of barium. Laboratory investigations showed evidence of malabsorption, hypoalbuminemia, and hypocalcemia. Two patients had no evidence of malabsorption. Nine patients had serum alpha heavy chain protein. However, intestinal fluid immunoelectropheresis and immunofluorescence studies on involved intestinal mucosa were not performed, and alpha heavy chain disease (αHCD) thus could not be excluded in the remaining 16 patients. A new staging classification is proposed, and the role of laparotomy in staging is emphasized. In five patients, mesenteric lymph nodes harbored immunoblastic sarcoma; in the same patients, a benign-appearing lymphoplasmacytic cellular infiltrate was present in the intestinal mucosa. Three patients had histologically proven lymphoma in the peripheral lymph nodes, and all had αHCD. Lymphomatous involvement of distant organs was not observed. One patient with αHCD was considered to be in the premalignant phase of IPSID. The prognosis was poor, as the majority of patients succumbed within 2 yr after diagnosis. The significance of early detection is emphasized.

3142 THE EFFECT OF JEJUNOILEAL BYPASS ON BILE COMPOSITION AND THE FORMATION OF BILIARY CALCULI. (Eng.) Wise, L.; Stein, T. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Ann. Surg.* 187(1):57-62; 1978.

The effect of jejunoileal bypass on the incidence of gallstone formation, on the frequency of cholesterol saturation, and on biliary lipid composition was investigated in 101 morbidly obese patients. Nine patients developed biliary calculi postoperatively during a mean follow-up period of 29.6 months. In eight consecutive patients, the lithogenicity of bile was assessed by methods that are dependent on cholesterol saturation. Postoperatively, the lithogenic score decreased in six and increased in two patients, one of whom developed gallstones. The biliary glycine/taurine ratio increased ($p<0.05$) from 4.6 to 5.9 postoperatively. These results suggest that the increased incidence of cholelithiasis following small bowel bypass is not only due to a relative change in bile composition but is probably more significantly due to an increase in the biliary glycine/taurine ratio and a consequent decrease in the biliary zeta potential.

3143 HEPATIC INTRAMITOCHONDRIAL FILAMENTS IN MORBIDLY OBESE PATIENTS UNDERGOING INTESTINAL BYPASS. (Eng.) Friedman, H. I.; Chandler, J. G.; Nemeth, T. J. (Letterman Army Inst. Res., Presidio of San Francisco, San Francisco, CA 94129). *Gastroenterology* 73(6):1353-1361; 1977.

To determine whether the presence of hepatocyte intramitochondrial filaments (IMFs) indicate a mitochondrial response to an altered cellular metabolic environment, the characteristics of these filaments were studied in 16 patients undergoing jejunal ileal bypass for morbid obesity. At the time of bypass, all of the liver biopsies showed varying degrees of steatosis, and IMFs were present in 13 of the 16 operative specimens. The IMFs were most prominent in the periportal cells, whereas the intracellular lipid was concentrated in centrilobular cells. Midzonal hepatocytes were intermediate in both respects. The IMFs were more abundant in biopsies showing moderate steatosis than in those with marked lipid accumulation in which the IMFs were limited to hepatocytes in juxtaposition to portal triads. The IMFs appeared to originate from mitochondrial cristae. When steatosis resolved 12 to 18 months after intestinal bypass, the prevalence of IMFs diminished also. The presence of IMFs may be ultrastructural evidence of an adaption to an altered metabolic environment, which resolves when the inciting influence is removed.

3144 ROLE OF CALORIC INTAKE IN THE WEIGHT LOSS AFTER JEJUNOILEAL BYPASS FOR OBESITY.

(Eng.) Condon, S. C.; Janes, N. J.; Wise, L.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Gastroenterology* 74(1):34-37; 1978.

To investigate the role of decreased caloric intake in the weight loss observed in patients after jejunoileal bypass for obesity, 65 patients were studied prospectively after this procedure. Dietary intake pre- and postoperatively was measured either directly by weighing food or by a research dietary history. Of 65 measurements, 59 were made at least 6 months after operation, when, over 75% of weight loss had been achieved. Fat absorption was measured in 42 patients. The entire group ate fewer calories (2,595 ± 135 cal) postoperatively than preoperatively (3,261 ± 138 cal). This difference was highly significant ($p<0.001$). Forty-eight patients ate less after their operation. The caloric deficit calculated from the observed weight loss could be accounted for entirely by the estimated decrease in intake in 22 of the 48 patients who ate less postoperatively. Moreover, measured fat malabsorption accounted for only 31% of the observed weight loss in those who ate more postoperatively and 21% in those who ate less. It is concluded that a decrease in caloric intake, along with malabsorption, is an important factor in the long term postoperative weight loss (1-9 months) after jejunoileal bypass for obesity.

3145 ABSENCE OF MUCOSAL ATROPHY IN HUMAN SMALL INTESTINE AFTER PROLONGED ISOLATION.

(Eng.) Tompkins, R. K.; Waisman, J.; Watt, C. M. H.; Corlin, R.; Keith, R. (Univ. California Los Angeles Sch. Medicine, Los Angeles, CA 90024). *Gastroenterology* 73(6):1406-1409; 1977.

Segments of isolated human jejunum (bypassed for 3.33 yr in treatment of morbid obesity) and ileum (bypassed for 6 yr as a Thiry-Vella fistula in treatment of postsurgical fistula) were examined histologically and ultrastructurally. There was no obvious evidence of widespread mucosal atrophy in either case. These findings contrast with those reported in experimental animals and in most human patients with ileal urinary conduits, where atrophy of the isolated segment is the rule. Nonluminal factors in humans may be sufficient to maintain small intestinal mucosa for long periods in the absence of intestinal chyme.

3146 IDIOPATHIC INTESTINAL PSEUDOOBSTRUCTION: RESPONSE TO DRUGS.

(Eng.) Lewis, T. D.; Daniel, E. E.; Sarna, S. K.; Waterfall, W. E.; Marzio, L. (McMaster Univ. Medical Center, 4W8, 1200 Main St., West, Hamilton, Ontario L8S 4J9, Canada). *Gastroenterology* 74(1):107-111; 1978.

Intraluminal recordings of motility were made from a patient with chronic idiopathic intestinal pseudoobstruction. Contractile activity was recorded from the esophagus and duodenum with and without cholinergic stimulation. Electrical activity was recorded from the duodenum with and without cholinergic stimulation. Contractile and electrical activities were recorded from the sigmoid colon at rest and after morphine administration (5 mg, i.v.). Gastric fundic relaxation was measured during balloon distention. This patient showed abnormalities of esophageal function similar to achalasia, while gastric fundic relaxation was impaired, with a more rapid rise in pressure on distention than was seen in five normal subjects. Duodenal and colonic electrical control and response activities were present on occasion. Duodenal contractions occurred in response to both bethanechol (5 mg, s.c.) and edrophonium (6-7 mg, i.v.). Therefore, the efferent cholinergic system of the small bowel appears to be functional in this case of idiopathic intestinal pseudo-obstruction. The nonadrenergic inhibitory control of esophagus and gastric fundus appears to be functioning abnormally.

3147 POSTOPERATIVE GASTROINTESTINAL ELECTRICAL AND MECHANICAL ACTIVITIES IN A PATIENT WITH IDIOPATHIC INTESTINAL PSEUDOOBSTRUCTION.

(Eng.) Sarna, S. K.; Daniel, E. E.; Waterfall, W. E.; Lewis, T. D., Marzio, L. (McMaster Univ. Medical Center, 4W8, 1200 Main St. West, Hamilton, Ontario L8S 4J9, Canada). *Gastroenterology* 74(1):112-120; 1978.

Studies were carried out, after laparotomy, *in vivo*, and *in vitro* on the stomach and small intestine of a patient with severe idiopathic intestinal pseudo-obstruction. Gastrointestinal electrical activities were recorded *in vivo* for 7 days postoperatively by 10 sets of bipolar electrodes implanted seromuscularly in the jejunum on both sides of an anastomosis, and in the stomach. The jejunal electrical control activity (ECA) frequency was very low (4.75 ± 5.34 cycles/min) and highly irregular immediately postoperatively, but its frequency and regularity improved over the next hour. Then ECA disappeared except during the occurrence of a migrating myoelectrical complex (MMC) at the recording sites. The mean duration of 28 MMCs was 5.91 ± 2.79 min. The mean interval between successive MMCs was 34.7 ± 18.9 min. Drugs like meperidine as well as small doses of prostaglandin $F_{2\alpha}$ (2.5 μg/min) initiated MMCs, whereas morphine, pentagastrin, and larger doses of prostaglandin $F_{2\alpha}$ initiated ECA with electrical response activity simultaneously at all electrodes. Feeding ice cubes or a cup of tea also induced irregular ECA with electric response activity superimposed on it. Electrical stimulation during the absence of ECA could not restore it. When ECA was present, electrical stimulation could decrease but not increase the frequency of ECA, presumably because it was maximal. *In vitro* studies on longitudinal and circular muscle strips from a segment of jejunum removed at laparotomy showed that the responses to transmural stimulation of intrinsic cholinergic or nonadrenergic inhibitory nerves and to drugs like acetylcholine, carbamoylcholine, physostigmine, serotonin, catecholamines, and ATP differed only quantitatively from responses to similar strips from normal small intestine. The total absence of ECA except during a MMC may be responsible for the motility disorder in this patient. Vagal activity may be essential for initiation of MMCs; if so, the efferent cholinergic system appeared to function. Idiopathic intestinal pseudo-obstruction did not result from primary impairment of muscle contractile function, or of receptors to nerve mediator function of intrinsic cholinergic or nonadrenergic inhibitory nerves. Hyperpolarization of intestinal smooth muscle may explain the absence of ECA and most other motility abnormalities in this patient.

3148 STAGNANT LOOP SYNDROME IN PATIENTS WITH CONTINENT ILEOSTOMY (INTRA-ABDOMINAL ILEAL RESERVOIR). (Eng.) Schjonsby, H.; Halvorsen, J. F.; Hofstad, T.; Hovdenak, N. (5016 Haukeland Hosp., Norway). *Gut* 18(10):795-799; 1977.

Intestinal absorption and bacteriology of the ileal contents were compared in seven patients with continent ileostomy and seven patients with conventional ileostomy. The absorption of vitamin B_{12} was reduced in five patients with continent ileostomy and subnormal in two patients with conventional ileostomy. Steatorrhea was present in four patients with continent and one patient with conventional ileostomy. Increased concentrations of total anaerobic bacteria and *Bacteroides* were found in the ileum of the patients with continent ileostomy. After a p.o. dose of $[1\text{-}^{14}C]$glycocholic acid there was no difference in the fecal excretion of radioactivity, whereas the $^{14}CO_2$-expiration was increased in two patients with continent ileostomy. In four patients with continent ileostomy and malabsorption of B_{12}, there was evidence of a stagnant loop syndrome, as p.o. lincomycin treatment resulted in increased absorption of B_{12}, decreased excretion of fecal fat, and decreased concentrations of *Bacteroides* in the ileum. These studies suggest that malabsorption was caused by the stagnant loop syndrome in four of the seven patients with a continent ileostomy.

3149 THE BRUSH BORDER MEMBRANE IN HEREDITARY SUCRASE-ISOMALTASE DEFICIENCY: ABNORMAL PROTEIN PATTERN AND PRESENCE OF IMMUNOREACTIVE ENZYME. (Eng.) Freiburghaus, A. U.; Dubs, R.; Hadorn, B.; Gaze, H.; Hauri, H. P.; Gitzelmann, R. (Gastrointestinal Unit, Univ. Berne, Berne, Switzerland). *Eur. J. Clin. Invest.* 7(5):455-459; 1977.

A micromodification of the Schmitz technique for the isolation of brush border membrane fragments allowed the investigation of the molecular mechanisms responsible for hereditary sucrase-isomaltase deficiency in a child with this disorder. The method allows the analysis of membrane proteins using as little as 10 μg of protein, which permits the study of the protein composition of isolated membrane fragments, the visualization of the enzyme *in situ*, and the measurement of the total enzymatic activity in the homogenate using a single biopsy specimen. Immunoreactive enzyme was present in the intact duodenal mucosa. Polyacrylamide gel electrophoresis carried out with membrane fragments of an intestinal biopsy showed an abnormal protein band without enzyme activity. The mucosa had a relatively high residual isomaltase activity, which was recovered from the gel in a position suggesting higher than normal molecular weight. The results indicate that, in this patient, the primary structural defect was in the sucrase moiety, which was enzymatically inactive. The isomaltase subunits may have aggregated into a large molecular weight complex because of unavailability of their partners. The observation also provides evidence for separate biosynthesis of the two moieties of the sucrase-isomaltase complex.

SMALL INTESTINE

Malabsorption

3167 TEST MEAL FOR ASSESSING INTRALUMINAL PHASE OF ABSORPTION IN CHILDHOOD. (Eng.) McCollum, J. P. K.; Muller, D. P. R.; Harries, J. T. (Inst. Child Health, 30 Guilford St., London WC1N 1EH, England). *Arch. Dis. Child.* 52(11):887-889; 1977.

A modification of the Lundh test meal for assessing the intraluminal phase of absorption in childhood was validated. The liquified meal is administered by nasogastric tube and contains carbohydrate (4%) in the form of glucose, protein (4%) as comminuted chicken, and fat (4%) as corn oil. One hundred thirty-two test meals were administered to 110 patients aged 2 weeks to 18 yr (mean age 4.3 yr). Ten children with suspected malabsorption, who were proven to be normal after extensive investigation, constituted the control group. The mean trypsin, amylase, lipase, and esterase activities in the controls were 46.4 μEq/min/ml, 34 IU/ml, 860 μEq/min/ml, and 1.6 μmol/min/ml, resp., while the levels in the cystic fibrosis patients were 2.4 μEq/min/ml, 7 μEq/min/ml, and 0.10 μmol/min/ml for trypsin, lipase, and esterase, resp. The total and individual bile salt concentrations for the controls are also presented.

3168 JEJUNAL VILLOUS ATROPHY AND GRANULOMATOUS INFLAMMATION RESPONDING TO A GLUTEN-FREE DIET. (Eng.) Bjorneklett, A.; Fausa, O.; Refsum, S. B.; Torsvik, H.; Sigstad, H. (Rikshospitalet, Arendal, Norway). *Gut* 18(10):814-816; 1977.

The case of a 48-yr-old women with intestinal malabsorption and subtotal to total jejunal villous atrophy, who also had granulomatous inflammation characterized by numerous epitheloid and giant cell granulomas in the stomach, the jejunum, and the liver, is presented. On a gluten-free diet, a complete remission was achieved that included disappearance of the granulomatous inflammation. The granulomas in this case may have been manifestations of the gluten intolerance.

3169 INTESTINAL ABSORPTIVE AND DIGESTIVE FUNCTION IN PERNICIOUS ANEMIA. (Eng.) Arvanitakis, C.; Lyford, C. L.; Folscroft, J. (Kansas Univ. Medical Center, Rainbow Blvd. at 39th St., Kansas City, KS 66103). *Am. J. Med.* 63(6):859-864; 1977.

The digestive and absorptive function of the small intestinal mucosa was examined in three patients with pernicious anemia to determine the functional correlates of the morphologic changes previously described. Digestive brush border enzymes (disaccharidases and leucyl-naphthylamidase) in jejunal biopsy specimens from the patients followed a normal distribution compared with those in 12 healthy volunteers. With the exception of one patient with mild steatorrhea, the rest of the absorption test results (serum carotene, D-xylose urinary excretion, 72-hr fecal fat, serum calcium, serum albumin, jejunal biopsy) were within the normal range. Jejunal perfusion studies, however, with glucose, sodium, and water showed intestinal secretion of sodium and water, i.e., net movement of sodium and water from the plasma to the lumen, in the presence of normal glucose absorption. Follow-up studies in two patients after treatment with vitamin B_{12} did not reveal any significant improvement in the absorption rates from the pretreatment period. This abnormality of sodium and water transport in pernicious anemia represents another intestinal defect of a systemic disease that is not corrected by vitamin B_{12} replacement therapy.

3170 SELECTIVITY OF SMALL INTESTINAL EXUDATE IN CELIAC DISEASE AND CROHN'S DISEASE. (Eng.) Kingham, J. G. C.; Loehry, C. A. (General Hosp., Southampton, SO9 4XY, England). *Am. J. Dig. Dis.* 23(1):33-38; 1978.

The small intestine exudates of three patients with celiac disease and three with proximal jejunal Crohn's disease were compared with three controls, to determine the relationship between increased intestinal permeability (manifesting itself as protein-losing enteropathy) and possible loss of selectivity with the severity of intestinal lesions. The exudates were collected by proximal small intestinal perfusion. Once a steady siphonage was established, 100 Ci ^{125}I-polyvinylpyrrolidone (PVP) was injected i.v. After 1 liter of perfusate was collected, a 10-ml blood sample was taken. Following fractionation into its different molecular weight components, PVP clearance curves for perfusate and plasma were determined. Patients with celiac disease and Crohn's disease showed a significant increase both in permeability and loss of selectivity compared to controls ($p<0.001$), the latter being more profound in celiac disease. It is hypothesized that gross abnormalities in mucosal epithelial cells lead to the increase in permeability and that thickening and functional derangement of the epithelial basement membrane is responsible for the loss of selectivity of the small intestine exudate in celiac disease.

3171 IMMUNOGLOBULINS IN THE JEJUNAL MUCOSA IN ADULT COELIAC DISEASE AND DERMATITIS HERPETIFORMIS AFTER THE REINTRODUCTION OF DIETARY GLUTEN. (Eng.) Lancaster-Smith, M.; Joyce, S.; Kumar, P. (Queen Mary's Hosp., Sidcup, Kent, England). *Gut* 18(11):887-891; 1977.

The changes in jejunal immunoglobulin production after the reintroduction of dietary gluten in treated patients with adult celiac disease (ACD) and dermatitis herpetiformis (DH) was investigated. Cells containing IgA, IgG, and IgM were measured and the distribution of extracellular and epithelial cell immunoglobulin was assessed in nine treated patients with ACD and nine with DH before and after gluten was reintroduced to the diet. Patients with ACD and DH frequently had IgM and IgG cells above the normal range even before re-exposure to gluten, although the range of IgA cells was normal. In both diseases, IgA and IgM cells increased after gluten with a proportionally greater rise in the latter, so that numbers of IgM cells, but not of IgA, exceeded the control range in all but one patient. There were increased quantities of IgA and IgM extracellularly in the lamina propria and in epithelial cells after challenge with gluten. Third component of complement was also found in some biopsies after re-exposure to gluten. These findings support the suggestion that gluten induces a humoral immunological response within the small intestinal mucosa and that both IgA and IgM systems are involved.

3172 MYOPATHY IN WHIPPLE'S DISEASE. (Eng.) Swash, M.; Schwartz, M. S.; Vandenburg, M. J.; Pollock, D. J. (London Hosp., E1 1BB, England). *Gut* 18(10):800-804; 1977.

The case of a patient with Whipple's disease who developed a myopathy that improved during antibiotic therapy is reported. The muscle biopsy showed mild type 2 fiber atrophy, type 1 fiber preponderance, variability in fiber size, and changes in the myofibrillar pattern of affected fibers. Interfascicular macrophages contained PAS-positive material. With the electron microscope these macrophages contained membranous inclusions and bacillary bodies, similar to those seen in the jejunal biopsy. The histological findings in this patient demonstrate the widespread involvement that may occur in the disease, but the precise relation of the myopathy to the inclusions found in the macrophages is uncertain.

LARGE INTESTINE

3179 FECAL MICROBIAL FLORA IN SEVENTH DAY ADVENTIST POPULATIONS AND CONTROL SUBJECTS. (Eng.) Finegold, S. M.; Sutter, V. L.; Sugihara, P. T.; Elder, H. A.; Lehmann, S. M.; Phillips, R. L. (Wadsworth Hosp. Center, Veterans Admin., Los Angeles, CA 90073). *Am. J. Clin. Nutr.* 30(11): 1781-1792; 1977.

Because colon cancer has been associated with high fat and animal protein in the diet and because the incidence of colon cancer in Seventh Day Adventists is known to be 60-70% of that in the general population, fecal flora were studied in 13 vegetarian Seventh Day Adventists and nonvegetarian Adventists. A separate study on fecal *Clostridium paraputrificum* involved a comparison of vegetarian Adventists (45) and non-Adventists on a conventional American diet (31). The Adventist groups had significantly fewer C. *septicum* and C. *tertium* isolates than the non-Adventists. Comparison with earlier diet studies revealed certain striking differences. Fusobacterium and C. *perfringens* counts were very low and lactobacillus counts very high in Adventists as compared with Japanese-Americans on either a Japanese or Western diet or Caucasian individuals on a conventional U.S. diet. Comparison of nonvegetarian Adventists with the other groups on a nonvegetarian Western diet also revealed several statistically significant differences. Finally, there were a number of significant differences in fecal flora when high risk groups (Japanese-Americans on Western Diet and Caucasians on conventional U.S. diet) were compared with low risk groups (Japanese-Americans on a Japanese diet and Adventists).

3180 COLORECTAL COMPLICATIONS OF RENAL ALLOGRAFT TRANSPLANTATION. (Eng.) Sawyerr, O. I.; Garvin, P. J.; Codd, J. E.; Graff, R. J.;

Newton, W. T.; Willman, V. L. (Dept. Surgery, St. Louis Univ., 1325 S. Grand Blvd., St. Louis, MO 63104). *Arch. Surg.* 113(1):84-86; 1978.

The cases of 113 patients with end-stage renal disease who underwent renal transplantation were reviewed to elucidate the incidence of colorectal complications and to determine the clinical course and outcome of these patients. One hundred twenty-five renal transplantations were performed in these patients between January 1968 and December 1975. Six patients had colorectal complications, and five of these patients died as a direct result. Chart analysis of these 113 transplant recipients identified 55 patients as having undergone colonic evaluation (contrast enema, postmortem examination). Seven of these 55 were found to have diverticulosis, and major colonic complications eventually developed in 4. Since the mortality from the complications of colorectal disease in immunosuppressed patients is so prohibitive, consideration should be given to exclusion from transplantation or to elective segmental colectomy prior to transplantation, regarding patients with diverticulosis and a previous history suggestive of diverticulitis.

3181 ADJUVANT LIVER PERFUSION IN COLORECTAL CANCER: INITIAL RESULTS OF A CLINICAL TRIAL.

(Eng.) Taylor, I.; Brooman, P.; Rowling, J. T. (Univ. Dept. Surgery, Liverpool L69 3BX, England). *Br. Med. J.* 2(6098):1320-1322; 1977.

Fifty consecutive patients with colorectal cancer but no evidence of secondary deposits in the liver were included in an ongoing controlled clinical trial of adjuvant liver perfusion with fluorouracil aimed at reducing the incidence of hepatic metastases. All patients underwent resection of the primary tumor. Twenty-six patients served as controls, and 24 received fluorouracil (1 g/day) as a continuous infusion into the portal venous system during the first 7 days after operation. The patients were matched for age, sex, and site and stage of the disease. The immediate postoperative mortality and morbidity did not differ significantly between the two groups. During the follow-up period (mean duration 15.5 months), however, six deaths occurred in the control group and only one in the perfusion group. At necropsy, four of the controls had multiple liver metastases. Two of the surviving controls developed evidence of liver metastases, and two had a local recurrence. No patient in the perfusion group developed evidence of hepatic metastases. These initial results suggest that adjuvant portal venous perfusion with fluorouracil may reduce the incidence of liver metastases in colorectal cancer.

3182 CHEMOTHERAPY AS AN ADJUVANT TO SURGERY FOR COLORECTAL CANCER: A FOLLOW-UP REPORT.

(Eng.) Lawrence, W., Jr.; Terz, J. J.; Horsley, J. S., III; Brown, P. W.; Romero, C. (Medical Coll. Virginia, Box 11, 1200 E. Broad St., Richmond, VA 23298). *Arch. Surg.* 113(2):164-168; 1978.

The results of an adjuvant program of fluorouracil for patients undergoing "curative" resection for adenocarcinoma of the colon and rectum that was initiated as a randomized clinical trial in January 1968 are presented. Patients were randomly assigned to an intraluminal fluorouracil or intraluminal control (saline) group and were so treated at the time of surgical resection, if findings at operation indicated that all gross neoplastic disease could be resected. Those patients receiving intraluminal fluorouracil (30 mg/kg) received i.v. fluorouracil (10 mg/kg) on each of the first 2 postoperative days and five subsequent postoperative courses of p.o. fluorouracil (90 mg/kg) in each 18-day course over a 1-yr period. By July 1, 1975, there were 203 patients undergoing curative resection entered into the study. Survival and disease-free data, as of December 31, 1976, revealed no benefit from this adjuvant course of fluorouracil. These data support the need for continued randomized clinical trials of new and innovative adjuvant therapy compared with an untreated control group.

3183 ENTEROGLUCAGON AND SUBSTANCE P-LIKE IMMUNOREACTIVITY IN ARGENTAFFIN AND ARGYROPHIL RECTAL CARCINOIDS.

(Eng.) Wilander, E.; Portela-Gomes, G.; Grimelius, L.; Lundqvist, G.; Skoog, V. (Univ. Hosp., P.O. Box 553, S-751 22 Uppsala, Sweden). *Virchows Arch.* [*Cell Pathol.*] 25(2):117-124; 1977.

The occurrence of substance P and enteroglucagon immunoreactivity was studied in rectal carcinoid specimens. A specific immunofluorescence for enteroglucagon or substance P or for both hormones was demonstrated in 9 of the 12 examined rectal carcinoids. One tumor was argentaffin, contained ultrastructurally pleomorphic granules of the enterochromaffin cell type, and showed immunofluorescence for substance P. The rest were nonargentaffin but were argyrophil with the Grimelius technique and contained round granules. The argyrophil carcinoids were immunoreactive to one or both hormones in eight cases and not fluorescent in three cases. In two of the nonargentaffin carcinoids, a small number of argyrophil cells was found with the Sevier-Munger method. The fact that substance P immunofluorescence is found in nonargentaffin carcinoids indicates that this substance can be produced in nonargentaffin endocrine cells or that the tumor cells of carcinoids have the potential to differentiate in several directions, with hormone production different from that of normal endocrine cells.

3184 HEREDITARY PROXIMAL COLONIC CANCER.

(Eng.) Lynch, P. M.; Lynch, H. T.; Harris, R. E. (Creighton Univ. Sch. Medicine, 2500 California St., Omaha, NB 68178). *Dis. Colon Rectum* 20(8):661-668; 1977.

Ten families prone to cancer of the colon (in the absence of familial polyposis coli) were investigated to document the site distribution of colonic cancers. A significantly greater frequency of carcinomas of the proximal colon was evident relative to nonfamilial colonic cancers (65% versus less than 35%, p<0.001). Moreover, family members with proximal colonic cancers experienced significantly enhanced survival, compared with family members with distal colonic or rectal cancers (68% versus 38%, p<0.01). Findings consistent with a genetic predisposition included early mean age at onset (45 yr) and a high frequency (40%) of multiple primary cancers in the patients studied. The results are in accord with reported findings in 11 similar kindreds from the literature, and strongly suggest the existence of a heritable variety of colonic cancer in which the proximal colon is at particularly high risk. Extraordinary early diagnostic measures, including colonoscopy, are indicated for members of such families.

3185 NONSPECIFIC PROCTITIS IN ASSOCIATION WITH IRRITABLE COLON SYNDROME. (Eng.)

Tandon, R. K.; Tandon, H. D.; Tandon, B. N. (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India). *Am. J. Proctol.* 28(6):29-35; 1977.

Sixty-four patients (male:female ratio=3:1) with nonspecific proctitis associated with irritable colon syndrome were studied. The lesion was limited to 1-2 cm of the terminal rectum, and a clear cut upper border was lacking. The affected mucosa appeared congested, with occasional excoriations or petechiae but was not friable and could not be scraped off. The most common symptoms were tenesmus (93.7%) and rectal urgency (81.2%). Streaking of stool with fresh blood was common (39.1%). No correlation could be made between the different grades of proctoscopic change and the severity or duration of symptoms. Seventeen rectal biopsies were examined histologically. The glands were irregular in their axial distribution, spacing, and size and in the types of cells constituting them. The appearance of the goblet cells suggested regenerative activity following mucosal erosion. There was also severe patchy mucosal edema, congestion and interstitial hemorrhage. There was no cryptitis or crypt abscess, no active mucosal ulceration, and no Paneth cell metaplasia. No known single parasite was detected in any significant number of the patients. The condition responded well to local fomentation, topical anesthetics, and correction of the bowel disturbances. It is likely that the localized, nonspecific inflammatory condition of the anorectal region in these patients may be producing increased colonic motility and thus perpetuating the problem of irritable colon.

3186 HEREDITARY POLYPOSIS COLI I: THE DIAGNOSTIC VALUE OF COLONOSCOPY, BARIUM ENEMA, AND FECAL OCCULT BLOOD. (Eng.)

Pavlides, G. P.; Milligan, F. D.; Clarke, D. N.; Cohen, S. B.; Wennstrom, C. J.; Burbige, E. J.; *et al.* (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD). *Cancer* 40(5, Suppl.): 2632-2639; 1977.

The diagnostic value of colonoscopy, barium enema, and the determination of fecal occult blood in patients at risk for hereditary polyposis coli was assessed in 225 patients from 157 families in whom polyposis had been diagnosed. There were 42 positive colonoscopies and 12 positive barium enemas, with both being positive in 10 subjects. There were 141 negative enemas and 133 negative colonoscopies, with 118 negative for both. Occult blood was positive in 30% of patients with polyposis, which was five to seven times more frequently than in those without evident polyposis. Colonoscopy detected polyposis in 30% of the progeny of affected people. The shortfall, compared with the 50% expected under the Mendelian hypothesis, is readily explained by removal of affected cases from the study by surgery or death from cancer.

3187 DUODENAL LESIONS IN FAMILIAL POLYPOSIS OF THE COLON. (Eng.)

Yao, T.; Iida, M.; Ohsato, K.; Watanabe, H.; Omae, T. (Dept. Internal Medicine II, Kyushu Univ., Maidashi 3-1-1, Higashi-ku, Fukuoka 812, Japan). *Gastroenterology* 73(5): 1086-1092; 1977.

The diagnosis and significance of duodenal lesions in familial polyposis coli were examined by performing hypotonic duodenography, duodenofiberscopy, and endoscopic biopsy in 14 patients with familial polyposis of the colon. In 13 patients, roentgenography or endoscopy revealed adenomas of various size in the duodenum. In the remaining patient, a biopsy specimen that was taken accidentally from the papillary region showed adenoma, although neither duodenography nor endoscopy revealed any abnormality. Adenomas in most cases were multiple and relatively small in size (<5 mm in diameter), and situated in the second portion of the duodenum, whereas a solitary and large adenoma was found in rare cases. This study strongly suggests that the incidence of duodenal lesions might be higher than that previously considered. In many cases, these lesions must have been overlooked, because the conventional technique of duodenography was not sufficient to detect such small adenomas. A high incidence of adenomatous lesions of the stomach or the duodenum and complications of benign or malignant tumors of various organs in familial polyposis of the colon may suggest that this disease is a systemic or generalized disorder rather than the disease of the colon per se. Therefore, the term "familial adenomatosis coli syndrome" seems to be more appropriate than "familial polyposis of the colon."

3188 PSEUDOULCERATIONS OF THE COLON ON BARIUM ENEMA EXAMINATION. (Eng.)

Frank, D. F.; Berk, R. N.; Goldstein, H. M. (Univ. Hosp., 225 W. Dickinson St., San Diego, CA 92103). *Gastrointest. Radiol.* 2(2):129-131; 1977.

Fine spiculations and punctate collections of barium projecting from the contour of the normal colon and simulating the appearance of ulcerations on barium enema examination are described. These may be due either to filling of the crypts of Lieberkuhn with barium or retention of barium in the innominate grooves of the colon. Perhaps both combine to produce the radiographic findings. This normal variant must be carefully distinguished from actual ulcers associated with inflammatory bowel disease to avoid making a major error in diagnosis.

3189 INTESTINAL TUBERCULOSIS: EXPERIENCE AT A CANADIAN TEACHING INSTITUTION. (Eng.) Schulze, K.; Warner, H. A.; Murray, D. (Univ. Iowa Hosp. and Clinics, Iowa City, IA 52242). *Am. J. Med.* 63(5):735-745; 1977.

Thirteen cases of inflammatory bowel disease suspected to be intestinal tuberculosis were analyzed. In nine patients, the diagnosis of tuberculosis was established from such criteria as caseation necrosis, positive acid-fast stains, or cultures of the diseased tissue. In four others, enteric tuberculosis remained a diagnostic possibility as judged by the following criteria: coexistence of the bowel lesion with established tuberculosis elsewhere; a clear response to antituberculous chemotherapy; and typical features on roentgenographic, surgical, or histologic examination. The patients with intestinal tuberculosis were not necessarily recent immigrants (all were either Canadian citizens or had immigrated at least 4 yr prior to developing the disease) or poor (at least 10 were middle-class), nor did they have coexistent active pulmonary disease. Although most exhibited classic features of intestinal tuberculosis, the diagnosis was rarely considered at first. A greater awareness of the entity is needed to avoid confusion between intestinal tuberculosis and Crohn's disease.

LARGE INTESTINE

Ulcerative Colitis

3206 LEUCOCYTE MIGRATION TEST WITH AUTOLOGOUS COLONIC MUCOSA AS ANTIGEN IN PATIENTS WITH ULCERATIVE COLITIS. (Eng.) Astrup, L.; Rasmussen, S. N.; Binder, V. (Frederiksberg Hosp., Ndr. Fasanvej 59, 2000 Copenhagen F, Denmark). *Scand. J. Gastroenterol.* 12(6):765-768; 1977.

Studies were carried out to evaluate the immunological parameters of ulcerative colitis by examining the patients' own colonic mucosa as a possible antigen and to determine whether a possible autohypersensitivity is specific to colonic mucosa. The leukocyte migration agarose technique (LMAT) was applied in a study of the migration of peripheral WBC in 16 patients with ulcerative colitis using three different autologous types of tissue as antigen: rectal, skin, and buccal mucosa. In all cases, the migration indices were within normal limits, and they did not differ from those in 12 controls with peptic ulcer, irritable colon, or hemorrhoidal tumors. The results do not support the theory of cellular hypersensitivity against colonic mucosa in patients with ulcerative colitis.

3207 SURGICAL MANAGEMENT OF TOXIC MEGACOLON. (Eng.) Roys, G.; Kaplan, M. S.; Juler, G. L. (Veterans Admin. Hosp., 5901 E. Seventh St., Long Beach, CA 90822). *Am. J. Gastroenterol.* 68(2):161-163; 1977.

Experience over the past 11 yr with 10 patients with chronic ulcerative colitis in whom toxic megacolon developed is presented. The patients were among a total of 220 patients admitted for chronic ulcerative colitis. Only 3 of the 10 patients had previously been treated with steroids. Steroid therapy reversed the acute process in three patients. All three patients later came to surgery. Toxic megacolon developed during the first episode of ulcerative colitis in 7 of the 10 patients. Three of the seven had colonic perforation prior to operation. Two patients died after a subtotal colectomy, and one died without operation. A delayed diagnosis was associated with sepsis in five patients and with all three deaths. Seven patients survived proctocolectomy. Prolonged medical management without a dramatic response appeared to correlate with a high postoperative morbidity. This study supports the concept of aggressive diagnosis and early surgical intervention for toxic megacolon.

3212 BILE, PANCREATIC CANCER, AND THE ACTIVATION OF PANCREATIC JUICE. (Eng.) Allan, B. M.; White, T. T. (Dept. Surgery, RF 25, Univ. Washington, Seattle, WA 98195). *Biochem. Biophys. Res. Commun.* 79(2):485-492; 1977.

Mechanisms involved in the activation of pancreatic juice following mixing with bile were investigated using pancreatic juice collected postoperatively from five patients and hepatic bile from two patients. Pancreatic juice specimens mixed with one of the bile samples (1:1) became activated at varying rates when incubated at 37 C. When the pancreatic juice specimens were mixed with the other bile sample, no active trypsin was found after 96 hr of incubation of 37 C. The bile that prevented activation had a high trypsin inhibitory capacity. Lower amounts of pancreatic secretory trypsin inhibitor (PSTI) were present in the samples of pancreatic juice that activated faster with the first bile sample tested. The data also suggest that increased amounts of trypsin-PSTI complex were present in the samples of pancreatic juice that activated faster. Thus, activation in the presence of bile depends on both the individual specimens and the proportions of bile and pancreatic juice used. When calcium was added to the incubation mixture, pancreatic secretions activated in a similar order as with the trypsin inhibitor-free bile. It is proposed that bile can only activate pancreatic juice following a trigger event of sufficient magnitude, such as carcinoma, to introduce trypsin or trypsin-like enzymes (i.e., plasmin) into pancreatic secretions, resulting in the formation of large amounts of the trypsin-PSTI complex.

3213 SERUM ALPHAFETOPROTEIN IN CYSTIC FIBROSIS OF THE PANCREAS. (Eng.) Brock, D. J. H.; Barron, L.; Manson, J.; McCrae, W. M. (Western General Hosp., Edinburgh EH4 2XU, Scotland). *Clin. Chim. Acta* 82(1/2):101-103; 1978.

Serum α-fetoprotein (AFP) concentrations were measured by three different types of radioimmunoassay in 30 patients with cystic fibrosis of the pancreas and in 55 controls to investigate the usefulness of AFP in the diagnosis and heterozygote detection in cystic fibrosis. The highest value obtained in a cystic patient was 10.2 ng/ml and in a control 10.8 ng/ml. These are within published normal limits. Previously reported large increases in serum AFP in patients with cystic fibrosis and in heterozygote carriers were not confirmed.

3228 RATIONALE FOR THE USE OF CIMETIDINE IN PANCREATIC INSUFFICIENCY. (Eng.) Regan, P. T.; Malagelada, J. R.; Dimagno, E. P.; Go, V. L. W. (Mayo Clinic, Rochester, MN). *Mayo Clin. Proc.* 53(2):79-83; 1978.

The use of an H_2-receptor antagonist cimetidine in conjunction with standard p.o. pancreatic enzyme replacement therapy to induce greater transgastric passage of ingested enzymes, resulting in improved intraluminal lipolysis, was tested in patients with advanced pancreatic insufficiency. The effects of p.o.-administered cimetidine were studied in two groups of patients using a double-marker perfusion technique. Cimetidine (200-400 mg/day) had no effect on postprandial exocrine pancreatic function in 16 duodenal ulcer patients without pancreatic disease. In six patients with pancreatic insufficiency, cimetidine produced a pronounced decrease in the output of gastric acid (-63.4%, $p<0.05$ in comparison with controls) and secretory volume (-44.9%, $p<0.05$), resulting in reduction of postprandial acidity and intragastric volume. These actions of cimetidine should retard or prevent inactivation of ingested enzymes and also increase their intragastric concentration, with resulting enhancement of luminal duodenal enzyme activity. Supplemental cimetidine may thus be useful in the medical management of patients who fail to respond to routine pancreatic extract therapy alone.

3229 SERUM PHOSPHOLIPASE A IN PATIENTS WITH ACUTE PANCREATITIS. (Eng.) Hashihira, S.; Nishii, T.; Takeda, Y.; Mori, R.; Wakabayashi, A. (Osaka Medical Coll., Takatsuki, Osaka, Japan). *Jpn. Arch. Intern. Med.* 24(7):243-249; 1977.

To examine the relationship between serum phospholipase A (PLA) and serum amylase levels and the clinical symptoms of acute pancreatitis, serum PLA and amylase activities were measured in 285 patients and one hundred normal controls. The test population consisted of patients with acute pancreatitis (11), chronic pancreatitis (30), cancer of the pancreas (10), other cancers (11), hepatic diseases (30), biliary diseases (20), peptic ulcer (15), pulmonary diseases (12), renal diseases (20), diabetes mellitus (19), and mumps (7). A normal distribution of serum PLA (6.8 ± 2.1 U/ml) and of serum amylase (131 ± 31 U) was observed in the controls so that the normal ranges were thus considered to be 2.6-11.0 U/ml and 69-193 U, resp., and ≥ 12 U/ml and ≥ 200 U were considered elevations of PLA and amylase, resp. Serum PLA levels were significantly elevated ($p<0.001$) in patients with acute pancreatitis, chronic pancreatitis, pancreatic cancer, and biliary disease (50.1 ± 23.0, 29.8 ± 37.5, 13.2 ± 5.6, and 16.2 ± 8.6 U/ml, resp.). Serum amylase levels were significantly elevated ($p<0.001$) in patients with acute pancreatitis, chronic pancreatitis, pancreatic calcification, biliary disease, peptic ulcer, renal disease, and mumps (906 ± 522, 241 ± 140, 97 ± 33, 201 ± 70, 161 ± 58, 222 ± 73, and 723 ± 294 U). In patients with acute pancreatitis, amylase levels returned to normal 5-6 days after onset, while PLA levels tended to lag behind recovery 4-5 days, showing a closer correlation with the change in symptoms than did amylase levels. Serum PLA determinations may be significant in the diagnosis of acute pancreatitis and as a pathophysiological index.

3230 INHERITED DEFECT IN HEREDITARY PANCREATITIS. (Eng.) Malik, S. A.; Van Kley, H.;

Knight, W. A., Jr. (St. Mary's Health Center, 6420 Clayton Rd., St. Louis, MO 63117). *Am. J. Dig. Dis.* 22(11):999-1004; 1977.

A new kindred with three definite and six suspected cases of hereditary pancreatitis (HP) was investigated for possible inherited abnormalities. No aminoaciduria (except for a slight rise in urinary histidine in 1 patient) and no hyperparathyroidism, hyperlipidemia, or chromosomal abnormality was present. An increase in the serum IgM level of a polyclonal type was noted in three definitely affected sisters and also in two nonaffected family members. Serum alpha-1-antitrypsin and serum trypsin inhibition were normal. However, very marked dilatation and ectasia of the pancreatic duct were found in the propositus. Reviewing the data from this family and previously described kindreds, it is postulated that the genetic abnormality in HP encompasses a wide variety of structural and anatomical defects in the sphincter of Oddi or the pancreatic ductal system. These predispose to intermittent obstruction of the duct with concomitant activation of enzymes and ductal metaplasia. In suspected cases, an early effort should be made to outline the pancreatic duct, as the defect may be amenable to surgery.

3231 DETECTION OF BACTERIAL INFECTION OF THE PANCREATIC DUCTS IN PATIENTS WITH PANCREATITIS AND PANCREATIC CANCER DURING ENDOSCOPIC CANNULATION OF THE PANCREATIC DUCT.

(Eng.) Gregg, J. A. (110 Francis St., Boston, MA 02215). *Gastroenterology* 73(5):1005-1007; 1977.

Studies were carried out in 35 patients with pancreatitis, 5 patients with pancreatic cancer, and 25 controls to determine whether bacterial infection of the pancreas occurs during nonsuppurative pancreatitis. During endoscopic cannulation of the main pancreatic duct, secretin was administered i.v., and pancreatic juice aspirated from within the duct was cultured. Bacterial infections were detected in 11 patients with pancreatitis and 3 with pancreatic cancer. The pancreatic juice was sterile in the controls. Cultures from the common bile duct in nine controls were also sterile, whereas four of six with pancreatitis showed infected bile. The infecting organisms were principally gram-negative, and the infections were usually polymicrobial. Antibiotics, where used, successfully eradicated the infecting organisms but did not appear to affect the patient's clinical course.

3232 SERUM AMYLASE ISOZYMES IN PATIENTS WITH CHRONIC PANCREATITIS WITH HYPERAMYLASEMIA.

(Eng.) Wakabayashi, A.; Saeki, M.; Mori, R.; Oshiba, S. (Second Dept. Medicine, Osaka Medical Coll., 2-7, Daigaku-cho, Takatsuki, 569 Japan). *Gastroenterol. Jpn.* 12(4):269-274; 1977.

Serum amylase isozymes were determined in 39 patients with chronic pancreatitis, including 13 with alcoholic pancreatitis, and in 23 healthy control subjects to clarify the relationship between hyperamylasemia and clinical states in chronic pancreatitis. The serum pancreatic type isoamylase (P-amylase) levels were 359 ± 109 IU/l in 7 patients with chronic pancreatitis in a state of acute exacerbation and 80 ± 43 IU/l in 32 patients with chronic pancreatitis in remission compared with a control value of 127 ± 19 IU/l. In all 39 patients, the serum P-amylase activity showed a positive correlation with the amylase secreting capacity of the pancreas. The serum-salivary type isoamylase (S-amylase) activity was higher in the acute exacerbation group (223 ± 120 IU/l) than in controls (123 ± 26 IU/l), but it was the same as the control value in the remission group (142 ± 66 IU/l) except for some cases that showed higher values. There were 10 patients who displayed hyperamylasemia, which was apparently due to the acute exacerbation in 7 cases. The serum P-amylase activity was high in all patients with acute exacerbation (range, 196-553 IU/l), and the serum S-amylase was also high in three of these patients (228, 256, and 475 IU/l, resp.). In three patients who had alcoholic pancreatitis and displayed hyperamylasemia without acute exacerbation, the P-amylase was low (14, 26, and 27 IU/l, resp.), and the S-amylase activity was markedly elevated (314, 324, and 351 IU/l, resp.). The ratio of amylase clearance to creatinine clearance was measured in 15 of the patients, and the values were within normal limits in all of the patients (1.48-4.20%). It is emphasized that hyperamylasemia in chronic pancreatitis may be caused by high S-amylase activity in addition to high P-amylase activity, especially in alcoholic pancreatitis.

3233 PRIMARY CHRONIC PANCREATITIS. A CLASSIFICATION BASED ON ENDOSCOPIC PANCREATOGRAPHY.

3252 IMMUNOLOGICAL CHANGES IN LIVER DISEASE. (Eng.) Sherlock, S. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Proc. R. Soc. Med.* 70(12):851-855; 1977.

Immunological changes in liver disease are reviewed. They may be induced either by liver damage, irrespective of the cause, or by specific factors present in any particular liver disease. The hypergammaglobulinemia observed in most cases of liver disease is probably caused by the failure of the damaged liver to clear antigens. The depressed cell-mediated (T-cell) immunity in chronic liver disease probably releases inhibition of B lymphocytes as a consequence of lack of suppressive T cells. In chronic active hepatitis, immunological changes are associated with a persistance of hepatitis B surface antigen (HBsAg) in the serum or with a negative HBsAg test. The following mechanisms of liver injury are presented: (1) direct action of complement fixing antibodies on the liver cell membrane, (2) formation of local immune complexes fixing complement, (3) T-cell mediated cytotoxity, and (4) antibody-dependent cellular cytotoxity. The latter mechanism seems to be the most important. Mechanisms of bile duct destruction in primary biliary cirrhosis are unclear. Smooth muscle antibody (SMA) is detected in high titers in two-thirds of patients with HBsAg-negative chronic active hepatitis (CAH). It is much less frequent and present in low titers in those with HBsAg-positive CAH. SMA can be found in low titers in 80% of patients with type A or B hepatitis. Mitochondrial antibodies occur in serum of 90% of patients with primary biliary cirrhosis, being a very important diagnostic test. Relatives of patients with either HBsAg-negative CAH or primary biliary cirrhosis show an increased incidence of antinuclear antibodies and SMA. In cryptogenic cirrhosis and CAH, an increased incidence of histocompatibility antigens HLA 1 and HLA 8 is observed. Autoantibodies against liver cell membranes were demonstrated in HBsAg-negative CAH and in cryptogenic cirrhosis.

3253 ALTERATIONS OF THE RESPIRATORY FUNCTION DURING HEPATOPATHIES WITH IMMUNE INVOLVEMENT. (Fre.) Nouvet, G.; Le Loet, C.; Pasquis, P.; Colin, R.; Bourreille, J.; Hemet, J.; *et al.* (Hopital Charles-Nicolle, 1, rue de Germont, 76038 Rouen Cedex, France). *Poumon Coeur* 33(3):175-182; 1977.

Respiratory function tests were performed in 24 patients with histologically confirmed chronic hepatitis. According to De Groote's classification, 13 patients had chronic aggressive hepatitis, 9 had chronic persisting hepatitis, and 2 had active posthepatic cirrhosis. The respiratory function was found to be normal in 2 patients only; 14 patients were found to have reduced alveolocapillary transfer capability, and 8 others had hyperinflation syndrome. The reduction of the alveolocapillary transfer may be due to diffuse interstitial pulmonary lesions that are observed in some cases of chronic hepatitis. This interstitial lesion obviously involves immune phenomena with participation of Australia antigen or other antigens. The hyperinflation syndrome, observed in four patients without past bronchopulmonary disease, is probably due to emphysema, whose association with chronic hepatitis has not been reported before.

3254 CANCER OF THE LIVER: PATHOGENESIS AND RECENT AETIOLOGICAL FACTORS. (Eng.) Anthony, P. P. (Middlesex Hosp. Medical Sch., London W1, England). *Trans. R. Soc. Trop. Med. Hyg.* 71(6):466-470; 1977.

The pathogenesis of experimental liver tumors and precursor lesions of liver cancer and the etiology of liver cancer in man are reviewed. The majority of chemical carcinogens require metabolic conversion to a reactive derivative by liver microsomal enzymes. Numerous different effects are produced in every part of the cell, but the most important is probably the damage to nuclear DNA. In experimental liver carcinogenesis, results depend on dose and rate of administration of a carcinogen, the species of the animals, age, sex, state of nutrition, and manipulation of the hormonal background or the rate of liver cell turnover. The process of carcinogenesis includes several phases of neoplastic initiation and development, which include initiation that produces altered hepatocytes, phenotypic changes, nodule formation, and the final cancer phase. Three populations of morphologically recognizable altered hepatocytes act at different stages of liver carcinogenesis. In man, a macronodular cirrhosis and hepatitis B are usually found in association with liver carcinoma. A familial occurrence of liver carcinoma was reported both with and without cirrhosis. There is no evidence that alcohol itself, without cirrhosis and malnutrition, increases the risk of liver tumor. It is also unclear whether iron overload and parasite infestations of the liver are associated with carcinoma. Several naturally occurring substances such as pyrrolizidine alkaloids, cycasin, safrole, some native remedia, and nitrosamines are among carcinogens. Liver tumors can be caused by such drugs and chemicals as the contrast medium Thorotrast, potassium arsenite in Fowler's solution, arsenical insecticides, vinyl chloride monomer, and anabolic/androgenic steroids.

3255 DEARTERIALIZATION OF THE LIVER FOR METASTATIC CANCER: CLINICAL, ANGIOGRAPHIC AND PATHOLOGIC OBSERVATIONS. (Eng.) McDermott, W. V., Jr.; Paris, A. L.; Clouse, M. E.; Meissner, W. A. (185 Pilgrim Rd., Boston, MA 02215). *Ann. Surg.* 187(1):38-46; 1978.

Experience with five cases of dearterialization of the liver for metastatic cancer is presented. Subjective and objective improvement in carcinoid syndrome for 2 yr was obtained in one patient who is living with extensive visceral and skeletal metastases 40 months after dearterialization. Excellent palliation was achieved in two other patients, one with carcinoma of the endometrium and the other with adenocarcinoma of the left colon; both died at 1 yr and 11 months, resp., after surgery. No improvement or palliation was observed in the two remaining patients. In one, the extent of dearterialization was inadequate, while in the other extensive necrosis of hepatic metastases was observed at postmortem examination. There was no evidence of serious damage to the hepatic parenchyma, either by liver function tests or by microscopy, as a result of interruption of arterial inflow. Microscopic observations of the tumors revealed extensive necrosis in all large tumor masses, but smaller nodules (less than 50 μm in diameter) maintained apparent viability. Postoperative angiographic studies revealed the difficulty in achieving complete dearterialization and the rapidity with which large collateral channels develop. Based on these arteriographic observations, the following operative procedure is recommended: dissection; identification and ligation of the common and proper hepatic arteries, the gastroduodenal artery, the right and left hepatic arteries, and the left gastric artery; and division of the triangular, falciform, and hepatorenal ligaments. This degree of devascularization should provide maximum effect on the tumor, and it was shown in two of the above cases that hepatic parenchyma survives even extensive dearterialization.

3256 BENIGN NON-PARASITIC CYSTS OF THE LIVER: A REVIEW OF 18 CASES. (Eng.) Wong, J.; Little, J. M. (Dept. Surgery, Univ. Sydney, Sydney, Australia). *Aust. N.Z. J. Surg.* 47(2):209-215; 1977.

Eighteen cases of benign nonparasitic cysts of the liver, seen during 1965-1974, are reviewed, with case histories given for four patients. Ten patients had the localized form and eight the generalized form of cystic disease. The ratio of women to men was 2:1 in both groups and the average age was 50. A correct preoperative diagnosis was made in five patients; in two patients with solitary cysts, the diagnosis was made at liver biopsy and in three polycystic patients, the diagnosis was made from their clinical features and investigatory findings. Associated conditions for which operation was necessary included carcinoma of colon or rectum (3), chronic duodenal ulcer (2), ruptured spleen, esophageal stricture, and lipoma of the ileocecal valve (1 each). Two patients died from complications of the cyst or of operations directed at the cyst: one from intrathoracic rupture of an abscess in the polycystic liver, and the other after cystojejunostomy, from cardiac and renal failure. Two of the patients suffered complications that have not been previously reported, i.e., abscess formation in a polycystic case and retrohepatic caval obstruction by a solitary cyst. Although many characteristics of the cysts in both solitary and polycystic groups are similar, the major differences are a positive family history, the association of cystic disease elsewhere, and the associated congenital anomalies in the polycystic group.

3257 HEPATIC GRANULOMATA: PROBLEMS IN INTERPREPARATION. (Eng.) Klatskin, G. (No affiliation given). *Mt. Sinai J. Med.* 46(6):798-812; 1977.

Problems in interpretation of hepatic granulomata are discussed and illustrated by a short review of data from 742 cases of biopsy-documented hepatic granulomata. The 565 cases of epithelioid granulomata were classified into three groups: (1) granulomatous disease (319 patients), (2) underlying hepatic disease (174), and (3) miscellaneous disorders of other etiology (72). In 177 cases, the lesions were diagnosed as lipogranulomata. A high incidence of hepatic granulomata (94%) was observed in sarcoidosis. However, such lesions gave rise to few clinical manifestations or hepatic impairment. The hepatic lesions in most forms of granulomatous disease were so similar that the diagnosis depended on the clinical features, serologic and skin tests, and bacterial and viral cultures rather than on histologic examination. Nonspecific granulomata can be found in primary biliary cirrhosis, Laennec's cirrhosis, acute viral hepatitis, and cytomegalovirus hepatitis. The third category of patients with granulomata were those whose underlying disease was primarily neither granulomatous nor hepatic in nature. These had lymphoma, carcinoma, ulcerative colitis, or Crohn's disease (19); acute viral or bacterial infections (8); psoriasis with gout and/or hyperuricemia (8); or disorders that defied diagnosis (37). In the latter cases, the hepatic granulomata may represent a nonspecific response to underlying disease or may be attributable to the action of some specific agent. The hepatic granulomata found in association with liver disease usually represent a nonspecific response to underlying disease.

3258 REGULATION OF BILE ACID SYNTHESIS IN HYPERLIPOPROTEINEMIA. (Eng.) Hellstrom, K.; Angelin, B.; Einarsson, K.; Kallner, M.; Leijd, B. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 235-239; 1977.

Bile acid kinetics were studied with the isotope-dilution technique and the serum triglyceride turnover with the [^{3}H]glycerol technique in patients with hyperlipoproteinemia (HLP). The formation of bile acid in HLP type IV, characterized by elevated levels of very low-density lipoproteins (VLDL), exceeded that seen in HLP types IIa (elevated levels of low-density lipoproteins [LDL]) and IIb (elevated levels of LDL and VLDL). The formation of triglyceride correlated significantly with that of bile acid (particularly with cholic acid) in HLP type IIa ($p<0.001$) and type IV ($p<0.01$) and in the combined series of patients ($p<0.001$). Further evidence of an integration between triglyceride and bile acid formation was obtained in HLP type II by studying regimens that may primarily increase (cholestyramine administration) or inhibit (chenodeoxycholic acid feeding) bile acid formation and in HLP type IV by studying regimens that inhibit (clofibrate or nicotinic acid treatment or weight reduction) or stimulate (carbohydrate-rich diets) the hepatic triglyceride formation.

3259 MALIGNANT PAPILLOMATOSIS OF THE INTRAHEPATIC BILE DUCTS.

(Eng.) Helpap, B. (Inst. Pathology, Univ. Bonn, Postfach 2120, D-5300 Bonn-Venusberg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 24(6):419-425; 1977.

A case of a woman born in 1934, with recurring intrahepatic bile duct papillomatosis involving the left hypoplastic hepatic lobe, is reported. A biopsy of the left lobe showed chronic cholangitis, pericholangitis, and biliary cirrhosis. Treatment included a left hemihepatectomy with excision of biliogastric and external fistulas. A gastroduodenal fistula developed that excreted 3 l of fluid daily, and the papillomatosis progressed to a mucin-secreting papillary adenocarcinoma. The patient died despite infusions of electrolyte solutions (6 l/day). A review of 12 previously described cases of extra- and intrahepatic bile duct papillomatosis is given, and it is suggested that these lesions be considered as low-grade carcinomas as soon as they are diagnosed.

3260 USE OF HEMATIN IN THE ACUTE ATTACK OF THE "INDUCIBLE" HEPATIC PORPHYRIAS.

(Eng.) Watson, C. J.; Pierach, C. A.; Bossenmaier, I.; Cardinal, R. (Northwestern Hosp., Minneapolis, MN). *Adv. Intern. Med.* 23:265-286; 1978.

The role of hematin (HT) in early termination of acute attacks of the "inducible" hepatic porphyrias was studied in 24 patients who had acute intermittent porphyria, porphyria variegata, or hereditary hepatic coproporphyria. An improved HT perfusion method was applied. The dose of HT per each infusion performed at 12 to 24 hr intervals was 4 mg/kg body weight and also depended on the clinical condition of the patient. The effect of HT depended on the amount infused per unit time. According to severity of neurologic symptoms, the following classes of the disease were encountered: (A) autonomic signs and symptoms, Gunther's triad, leg pain, paresthesis, restricted paresis, psychiatric manifestations, and mild hypertension; (B) autonomic signs, severe peripheral neuropathy, quadriparesis, hypertension, tachycardia, urinary retension, dysuria, obstipation, psychotic seizures, and inappropriate antidiuretic hormone syndrome (IADHS); and (C) life-threatening central, peripheral and autonomic disturbances, extensive paralysis, quadriparesis, psychotic symptoms, seizures, IADHS, and disturbed consciousness or coma. Selected case reports are presented. In cases of class A severity, one to three infusions were sufficient to cause a prompt recovery, while in cases of class B or C, a very slow but considerable improvement was observed after four to eight HT infusions. Infusion of HT is a valuable treatment in acute attacks of the hepatic porphyrias.

3261 LIVER ULTRASTRUCTURE IN PSORIATICS RELATED TO METHOTREXATE THERAPY. 1. A PROSPECTIVE STUDY OF FINDINGS IN HEPATOCYTES FROM 24 PATIENTS BEFORE AND AFTER METHOTREXATE THERAPY.

(Eng.) Nyfors, A.; Hopwood, D. (Dept. Dermatology, Finson Inst., Copenhagen, DK-2100, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(6):787-800; 1977.

Liver biopsies from 24 psoriatics with severe psoriasis before and after methotrexate (MTX) therapy were studied by light and electron microscopy. MTX apparently caused hepatocyte damage, which was reflected by the increased number of membrane whorls ($p<0.05$) and the increased accumulation of lipid droplets ($p<0.05$) observed in the patients' hepatocytes in comparison with that in controls. There was an increase ($p<0.05$) in autophagic vacuoles, which mostly contained glycogen and cell sap with residual bodies. These residual bodies were found in an increased number in the nearby Kupffer cells. Crystals occurred in megamitochondria in most patients before and after MTX therapy. Some of these crystals were found free in the cytoplasm. Mitochondria containing crystals were shown in autophagic vacuoles, representing possible pathways of their breakdown. Bile canaliculi commonly contained debris, but only one patient had evidence of cholestasis. There was no significant change in nuclei, Golgi apparatus, or the endoplasmic reticulum and no statistically significant correlation between the changes in the treated patients and the total dose of MTX given.

3262 LIVER ULTRASTRUCTURE IN PSORIATICS RELATED TO METHOTREXATE THERAPY. 2. FINDINGS IN BILE DUCTS FROM 11 METHOTREXATE TREATED PSORIATICS AND 2 CONTROLS.

(Eng.) Hopwood, D.; Nyfors, A. (Dept. Dermatology, Finson Inst., Copenhagen, DK-2100 Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(6):801-811; 1977.

Liver biopsy specimens from 11 psoriatics receiving methotrexate (MTX) were studied with the light and electron microscope and compared with normal material. Thick sections (1 μm) showed light and dark cells in biliary epithelium and lipofuscin granules. At the ultrastructural level, the presence of these structures was confirmed. The lumen of the bile ducts contained debris. The microvilli were decreased in number, and damaged forms were seen. Damage to the biliary epithelial mitochondria was widespread, and there were foci of intracellular edema. The Golgi apparatus was hypertrophied and dilated. Atrophic cells were seen. The lateral intercellular spaces were dilated and contained debris, and the basement membrane showed zones of duplication. Similar changes were found in the ducts of Hering.

3263 THE COAGULATION DISORDER OF ORTHOTOPIC HEPATIC TRANSPLANTATION.

(Eng.) Bohming,

H. J. (Krankenhaus Amstetten, A-3300, Austria). *Semin. Thromb. Hemostas.* 4(1):57-82; 1977.

Coagulation data in clinical and experimental liver transplantation accumulated over the last 14 yr are reviewed, and coagulation findings in a new series of 10 human liver recipients are presented. Systemic fibrinolysis is transiently induced during orthotopic hepatic transplantation, but its significance for the generation of coagulation changes and consecutive hemorrhages has been questioned. Intravascular coagulation has been encountered both during recipient hepatectomy (particularly the anhepatic phase) and after revascularization of the graft. In human liver transplantation, exogenous heparin as well as fibrin degradation products probably account for the prolongation of thrombin time, which often is encountered after revascularization of the hepatic graft. Bleeding was significant in all 10 patients during recipient hepatectomy and again, in some of them, after revascularization of the graft. The instant incoagulability of the recipient's blood, which was noted as soon as the liver had been revascularized in four new cases, was due to heparin contained in the solution used for the graft perfusion; this kind of anticoagulant activity was not observed in those recipients who had been given livers perfused with heparin-free solutions. The severity as well as duration of the coagulation changes following orthotopic hepatic transplantation depend primarily on the quality of the donor organ, with an adequately preserved liver almost instantaneously resuming its functions.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

3299 TREATMENT OF CRIGLER-NAJJAR SYNDROME. (Ger.) Plochl, E.; Hohenwallner, W. (Kinderspital der Landeskrankenanstalten Salzburg, Mullner Hauptstrasse 48, A-5020 Salzburg, Austria). *Wien. Med. Wochenschr.* 128(3):70-73; 1978.

Crigler-Najjar syndrome was diagnosed in a 6-week-old baby girl. Phenobarbital therapy proved to be ineffective. Phototherapy (3,700 lux, 150 W) was effective; it reduced the serum bilirubin level to below 20 mg% by the age of 14 months, but retardation of mental development and of motor function could not be prevented. The findings indicate the importance of early diagnosis of Crigler-Najjar syndrome (before the age of 6 weeks).

3300 MITOCHONDRIAL PATHOLOGY IN THE LIVER IN A PATIENT WITH THE DUBIN-JOHNSON SYNDROME. (Eng.) Enat, R.; Barzilai, D. (Rambam Medical Center, Technion-Israel Inst. Technology, Haifa, Israel). *Isr. J. Med. Sci.* 13(12):1197-1205; 1977.

The mitochondrial pathology of a liver biopsy from a 52-yr-old woman with the Dubin-Johnson syndrome is described. Electron microscopy showed in some hepatocytes an accumulation of typical Dubin-Johnson pigment that was composed of three elements: dark material as broad masses, light areas as fine granules, and homogenous fat-like droplets. Some cells showed dilated smooth endoplasmic reticulum. Although many cells did not show any abnormality, there were cells, mainly those with Dubin-Johnson pigment, with multiple vacuoles (0.4-25.5 μm in diameter) at the vascular poles of the cells. These vacuoles were either fat droplets or, in the majority of cases, included debris composed of sparse fine granular material, clumps of dense material, and multiple membranes. Many of these vacuoles were enclosed by a double membrane. Although many mitochondria appeared normal, there were others that showed disintegration of the matrix with partial to complete loss of mitochondrial cristae, lucent areas, isolated mitochondrial membranes, membranous whorls, and myelin figures. Severe mitochondrial damage as described above has not been reported in the hepatocytes of patients with the Dubin-Johnson syndrome, and it is recommended that mitochondrial damage be looked for in future electron microscopy studies of liver biopsies from patients with the Dubin-Johnson syndrome.

Nonviral Hepatitis and Hepatic Injury

3302 PATHOLOGY AND BIOCHEMISTRY OF PARACETAMOL-INDUCED LIVER DAMAGE. (Eng.) Williams, R.; Davis, M. (King's Coll. Hosp. Medical Sch., London, England). *Proc. Eur. Soc. Toxicol.* 18:27-40; 1977.

Clinical and experimental studies on paracetamol (acetaminophen, *N*-acetyl *p*-aminophenol) overdose and the treatment and prevention of overdoses are reviewed. The effects of a paracetamol overdose vary from a trivial clinical illness to severe fulminant hepatic failure, which carries a mortality of 80% or higher. In the less severely affected patients, there is necrosis of hepatocytes in the centrilobular areas, while in those who progress to fulminant hepatic failure, wide areas of confluent necrosis are seen. Survival is unlikely if more than 60% of liver cells are necrotic. If the patient survives the acute illness, liver function and structure return completely to normal. Paracetamol overdose produces hepatic necrosis by a direct action on the liver; its effects are dose related. The quantity of paracetamol metabolite bound within the liver, which correlates with the degree of hepatic necrosis, increases in proportion to the rate of urinary excretion of cysteine and mercapturic acid conjugates of the drug, suggesting that hepatic damage from paracetamol is due to overproduction of the reactive precursor of these conjugates. Neither depletion of hepatocellular glutathione nor covalent binding of the reactive paracetamol metabolite will produce hepatocellular necrosis if present singly, but, if they coexist, hepatic damage will ensue. Current treatment depends chiefly upon the administration of compounds that will substitute for hepatic reduced glutathione.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

3306 VIRAL HEPATITIS RESEARCH LEADING TOWARDS CONTROL BY VACCINATION. (Eng.) Melnick, J. L.; Hollinger, F. B.; Dreesman, G. R. (Baylor Coll. Medicine, Houston, TX 77025). *Arch. Roum. Pathol. Exp. Microbiol.* 35(1/2):5-65; 1976.

Studies that may result in the eventual control of hepatitis viruses A and B by vaccination are reviewed. The physicochemical characteristics of both virus types are discussed, including the composition of the hepatitis virus B particle and its antigenic determinants, collectively termed hepatitis B surface antigen (HBsAg). HBsAg is composed of several distinct antigenic specificities, but antibody to one of them, a group-reactive determinant (a), confers protection against all subtypes. The recently discovered e antigen can be used to determine the infectivity of blood. Anti-e seems to indicate that the blood is noninfectious even if HBsAg is circulating. The results of laboratory tests, including tests for liver function, tests for hepatitis type B and its antigens, and tests for hepatitis type A, and studies of the serological events in hepatitis B infection, virus-host immune reactions, and epidemiology, all contribute to the development of a possible vaccine for future control of hepatitis B. A new concept has developed for producing a virus vaccine: an immunizing antigen can be obtained from healthy carriers, preferably those possessing anti-e antibodies. However, immunization with purified 22-nm whole-particle preparations of HBsAg should be approached with extreme caution. The feasibility of using specific subunits derived from 22-nm HBsAg-containing particles should be investigated as a possible alternative vaccine.

3307 THE EPIDEMIOLOGY OF HEPATITIS B INFECTIONS IN A POLY-ETHNIC POPULATION. (Eng.) Banffer, J. R. J.; Brunings, E. A.; Gielis-Proper, F. K.; Schmitz, P. I. M. (Municipal Lab. for Epidemiological Bacteriology, c/o Public Health Service, P.O. Box 333, Schiedamsedijk 95, Rotterdam, Netherlands). *Am. J. Epidemiol.* 106(6):507-511; 1977.

Blood samples collected from 765 male donors of varying ethnic groups residing in Paramaribo, Surinam were analyzed by radioimmunoassay for hepatitis B surface antigen (HBsAg). Hepatitis B antibodies (anti-HBs) were determined in 738 of the donors. The prevalence of HBsAg in Indian donor subjects of Creole origin, subjects of mixed origin, Bushland Creoles, and Indonesians was 2.9, 3.6, 5.7, 8.1, and 18.6%, resp. If the Indonesians were excluded, there was no statistically significant difference among the other groups as estimated with the Spitz-L test. The difference between those groups and Indonesians was significant ($0.001<p<0.01$). Anti-HBs showed the highest prevalence in Indonesians

(61.3%) and was 34 and 26% in Creoles and Indians, resp. No significant difference was found between these groups if the Indonesians were excluded. Prevalence of anti-HBs in Indonesians was significantly higher than in other ethnic groups (p<0.001). The prevalence of HBsAg and anti-HBs in Creoles and mixed groups increased with age. Since a genetic hypothesis of greater prevalence of HBsAg and anti-HBs in Indonesians has previously been ruled out, it is suggested that family clustering in this ethnic group results in a greater exposure risk to hepatitis B virus.

Chronic Hepatitis

3329 PATHOGENETIC ASPECTS AND IMMUNOSUPPRESSIVE TREATMENT OF CHRONIC ACTIVE HEPATITIS. (Ita.) Miglio, F.; Facchini, A.; Stefanini, G. F.; Mariani, E.; Gasbarrini, G. B.; Labo, G. (Istituto di Clinica Medica e Gastroenterologia, Universita, Bologna, Italy). *Recent. Prog. Med. (Roma)* 62(4): 471-488; 1977.

The results of therapeutic trials with immunosuppressive drugs in the treatment of chronic active hepatitis are reviewed, and the preliminary results of a recent trial are presented. Prednisolone (15 mg/day) and azathioprine (75 mg/day) were compared in one trial in 47 patients. The findings demonstrated the higher effectiveness of prednisolone; it produced a greater reduction of the gamma-globulin level, lower incidence of esophageal varices, and a 2-yr survival rate of 95% (versus 72% in the azathioprine-treated group). New trials are being conducted with prednisolone (30 mg/day for 30 days, then 15 mg/day continuously), azathioprine (100 mg/day), and their combination (50 mg azathioprine plus 15 mg/day prednisolone for 30 days, then maintenance therapy with the same azathioprine dose plus 7.5 mg/day doses of prednisolone). The preliminary results indicate a good correlation between the lymphocytotoxicity test and the indices of necrosis, and parallel reduction of the cytotoxicity and of the SGOT level during the therapy.

3332 ROUTINE DIAGNOSIS AND THERAPY OF FATTY DEGENERATION OF THE LIVER. (Ger.) Gunthner, W.; Dandl, M. (Medicus-Hausl, 8240 Schonau, W. Germany). *Therapiewoche* 27(35):6084-6086, 6089; 1977.

Ten patients with fatty degeneration of the liver were placed on low-carbohydrate diets with abstinance from alcohol and they received betaine citrate (15 g/day during the first month, 7.5 g/day during the following 3 months). Fatty liver, diagnosed bioptically, was due to chronic alcohol abuse in eight cases, and to hyperalimentation in two. Four patients had hepatomegaly before the treatment, and the gamma-glutamyl level, measured in seven cases, was 16-163 U/l. Three patients lost weight considerably, and thus they were assumed to have kept the diet and abstained from alcohol, while these events are questionable in the other cases. The blind liver biopsy performed after the 4-month treatment revealed considerable reduction of the fat incorporation in the liver; the fat content dropped to 10% or less in eight cases. No hepatomegaly was seen. The results of the laboratory tests were largely contradictory, but the gamma-glutamyl level showed a reduction. The findings indicate the value of blind liver biopsy in the follow-up of fatty liver.

LIVER AND BILIARY TRACT

Cirrhosis

3336 ORAL CHOLATE TOLERANCE TEST--AN APPLICATION OF SPECIFIC RADIOIMMUNOASSAYS FOR THE DETERMINATION OF SERUM-CONJUGATED CHOLIC AND DEOXYCHOLIC ACIDS. (Eng.) Matern, S.; Haag, M.; Hans, C.; Gerok, W. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12, October 1976.* (Baltimore, Md.: University Park Press): 253-261; 1977.

The kinetics of serum conjugated cholic and deoxycholic acids were determined using specific radioimmunoassays in an oral cholate tolerance test to investigate the dynamics of the enterohepatic circulation of cholic acid in health and disease. In nine healthy volunteers, cholate administration (0.5 g p.o.) caused an elevation of peripheral serum conjugated cholic acid levels. In 10 cirrhotic patients without portal hypertension, the same dose caused a slightly higher increase of serum conjugated cholic acid than in the healthy volunteers. Cirrhotic patients with portal hypertension, however, had a marked elevation of serum conjugated cholic acid levels within the first hour after p.o. cholate administration. The kinetics of serum conjugated cholic acid in cirrhotic patients with portal hypertension showed a biphasic rise, with the second peak ascribed to the reabsorption of the cholate. The second peak reflects, therefore, a disturbed gallbladder function. In healthy volunteers, there were no changes of serum conjugated deoxycholic acid levels over a 5-hr period; in cirrhotic patients with portal hypertension, a very small part of the cholic acid was metabolized to deoxycholic acid during the enterohepatic circulation as demonstrated by a slight increase of serum conjugated deoxycholic acid levels over a 5-yr period. Changes in the levels of serum bile acids appear to reflect the dynamics of the enterohepatic circulation.

3337 SPLENOPORTOSCINTIGRAPHY: RESULTS IN 213 CASES. (Fre.) Vinot, J. M.; Paraf, A.; Syrota, A.; Desgrez, A. (Centre Hospitalo-Universitaire de Bicetre, F 94270 Le Kremlin Bicetre, France). *Ann. Med. Interne (Paris)* 128(12):917-921; 1977.

Splenoportoscintigraphic tests were performed in 213 patients, including 12 with hepatosplenic diseases, 23 with isolated splenomegaly, 18 with generalized diseases with hepatosplenic involvement, 11 with pancreatic diseases, 124 with cirrhosis (including 2 with biliary cirrhosis), 18 with portacaval shunt, 5 with fibrosteatosis, and 2 with cavernomas. Following the i.v. injection of ^{99m}Tc-labeled colloidal sulfur, the center of the spleen was marked, and ^{99m}Tc-labeled human albumin (1 mCi) and ^{99m}Tc-labeled RBC (12 mCi) were injected into the spleen. The scintigraphic test was a total failure in 8 cases due to the absence of any tracer migration and a partial failure in 13 cases due to the absence of the migration of one tracer. Hemoperitoneum prompted splenectomy 24 hr after the test in one case. In the evaluable cases, it was possible to determine the permeability of the anastomosis in portacaval shunt, and to obtain morphological and hemodynamic data. Umbilical reflux was found in 20/124 cirrhotic patients, and total spontaneous splenocaval shunt was found in 14/124 cases. The findings indicate the value of the splenoporto-scintigraphic test in the diagnosis of morphological and hemodynamic disorders in the portal circulation.

3338 MECHANISM OF HYPOGONADISM IN CIRRHOTIC MALES.

(Eng.) Green, J. R. B. (St. Bartholomew's Hosp., London, England). *Gut* 18(10): 843-853; 1977.

Recent studies on the mechanism of hypogonadism and feminization in cirrhotic males are reviewed. Associated with the clinical signs of hypogonadism and overt feminization in cirrhotic males is a reduced production of testosterone along with a low plasma testosterone concentration. Recent studies have failed to show significant changes in the hepatic metabolism of biologically potent estrogens in cirrhotic men, and there is no clear evidence of increased circulating concentrations of estrogens in cirrhotic men. Alcohol consumption appears to play no specific role in the endocrine changes of established cirrhosis, since these changes are seen equally in nonalcoholic cirrhotics. In noncirrhotic men, both short-term and chronic consumption of alcohol induce a variety of biochemical effects on sex hormone metabolism; many of the endocrine consequences of alcohol consumption in noncirrhotics may result from changes in the hepatic synthesis of sex hormone binding globulin. The pathogenesis of endocrine changes in cirrhotic men may be multifactorial, e.g., a combination of decreased hepatic clearance of some estrogenic compounds, an autoimmune-mediated primary testicular defect, and a specific potentiation effect by alcohol. Alternatively, none of these suggested mechanisms may be of importance, and the endocrine changes seen in cirrhotic males may be mediated by other undiscovered or unconsidered mechanisms.

3339 SERUM POLYAMINE AND OCTOPAMINE CHANGES FOLLOWING PARTIAL HEPATECTOMY AND PORTACAVAL SHUNT.

(Eng.) Monson, R. C.; Rodgers, B. M.; Garnica, A. D.; Talbert, J. L. (Dept. Surgery, Univ. Florida, Gainesville, FL). *J. Pediatr. Surg.* 12(6):1079-1084; 1977.

The effect of portal blood flow on liver regeneration was studied to determine the factors influencing hepatic regeneration following major hepatic resection. An end-to-side portacaval shunt was performed in a 5-yr-old boy to relieve splanchnic congestion resulting from interruption of the portal vein due to complete resection of the right lobe of the liver. Serial liver scans demonstrated that the right lobe was completely regenerated by 6 weeks postoperatively. Throughout the postoperative period, the patient was maintained on a high-protein diet without clinical evidence of hepatic encephalopathy. Serum ammonia and octopamine levels showed early mild elevations (32-90 μg/dl and 1.0-4.0 ng/dl compared to normal values of 18-48 μg/dl and 0.72-1.92 ng/dl, resp.), reaching maxima at 10-12 weeks and returning to normal limits by 20 weeks. Serum polyamine levels provided biochemical evidence of regeneration: an early rise, at 1-4 weeks, in the serum spermidine level (corresponding to the proliferative phase of rapid hepatocyte regeneration) was followed by a large elevation in serum spermine level, which began at 4-5 weeks, and is inversely related to hepatocyte growth and corresponds to the maturation phase of regeneration. The significance of polyamines as regulatory molecules is discussed; they appear to be useful markers for assessing hepatic regeneration. Serial determination of octopamine as an indicator of hepatic encephalopathy is proposed and discussed.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

3352 COMPLICATIONS OF ENDOSCOPIC SPHINCTEROTOMY. (Eng.) Liguory, C.; Girault, F.; Coffin, J. C. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, France, 8-9 June 1976.* (Basel: S. Karger): 232-239; 1977.

Complications of endoscopic sphincterotomy encountered in several series of patients are discussed. Hemorrhage is the chief complication of this procedure, occurring in 24/624 operations in three separate series. Acute pancreatitis represents 1.6% of complications of endoscopic sphincterotomy. Two kinds of infectious complications may occur: cholangitis and cholecystitis (when the gallbladder has been left). Perforation, generally retroperitoneal, was seen in 1.2% of cases. Blocking was observed in three cases and resulted from an insufficiently large sphincterotomy for the size of the stone. Although insufficient time has elapsed since the introduction of this technique to evaluate later complications, two risks are considered possible, secondary papillary stenosis and duodenal-biliary reflux. Some mishaps occurring with surgical sphincterotomy do not occur with endoscopy, e.g., complications associated with general anesthesia and surgery. Acute pancreatitis occurs after endoscopic sphincterotomy but is much less severe than after surgery. It is concluded that the risks of endoscopic sphincterotomy should not overshadow its benefits.

3353 EXPERIENCE WITH ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATICOGRAPHY. (Nor.) Ruud, T. E.; Rosseland, A.; Thorsen, G. (Telemark Sentralsjukehus, Kirurgisk avdeling, Skien, Norway). *Tidsskr. Nor. Laegeforen.* 97(33):1732-1735; 1977.

Experience with endoscopic retrograde cholangiopancreaticography (ERCP), performed in 133 patients on 155 occasions, is presented. Cannulation of the ampulla of Vater and contrasting of at least one duct system was possible in 89% of all cases. Cannulation was not possible in 29 cases, because the ampulla was not found, it was hidden in a duodenal diverticulum, or destroyed by tumor infiltration. Postcholecystectomy syndrome; suspect tumor of the bile ducts, pancreas, or duodenum; papillotomy, extrahepatic cholestatic jaundice; and examination after pancreatitis were the indications for ERCP. It was possible to visualize the pancreas in 85%, the bile ducts in 82%, and both systems in 70% of the cases. During visualization of the common bile duct, stone in the common bile duct was found in 21 cases, stone in the gallbladder in 9, dilated bile ducts in 30, stricture in 9, and no change in 34. The pancreas, visualized in 61 cases, showed chronic pancreatitis in 11 cases, pancreatic tumor in 5, tumor in the region of the ampulla of Vater in 1, and no change in 44 cases. The complications of ERCP occurred in 5% of the cases and included mild pancreatitis (3 cases), cholangitis (2), cardiac infarction (1), and fatal perforation of the common bile duct (1). ERCP was most useful in extrahepatic cholestasis. The examination helped establish the indication of surgery or spare the patient from surgery. A remarkably high incidence of pathological processes was found in patients with duodenal diverticulum. The findings indicate the great diagnostic value of ERCP.

3354 CLINICAL INVESTIGATIONS ON THE CHOLERETIC FEBUPROL. (Ger.) Scholing, W. E.; Weinert, W. (Kreuzbergpromenade 13 A, A-5020 Salzburg, Austria). *Munch. Med. Wochenschr.* 120(5):143-146; 1978.

The choleretic agent Febuprol (3-butoxy-1-phenoxy-propanol-[2]) was studied in 50 outpatients with cholecystopathy in a double-blind cross-over trial. Postcholecystectomy syndrome was diagnosed in 43 patients, chronic cholecystitis in 5, and cholecystopathy of unknown genesis in 2. Some patients received three capsules daily for 14 days, others received placebo, after which the drugs were switched. The therapeutic effectiveness was evaluated on the basis of a grade system, using feeling of fullness, pressure in the upper abdomen, meteorism, obstipation, flatulence, and postprandial nausea as criteria. The reduction of the intensity of these symptoms ranged from 0% (postprandial nausea) to 21.7% (flatulence) in the placebo group, while it ranged from 21.4% (meteorism) to 83.3% (postprandial nausea) in the Febuprol-treated group. The differences were statistically significant ($p<0.01$-0.05). The findings indicate the therapeutic effectiveness of Febuprol in cholecystopathy.

3355 GALLSTONE DISEASE: PATHOGENESIS AND MANAGEMENT. (Eng.) Shaffer, E. A.; Small, D. M. (McGill Univ., Montreal, Canada). *Curr. Probl. Surg.* 13(7):1-72; 1976.

The pathogenesis and treatment of gallstone disease, which accounts for 5,000-8,000 deaths per year, is reviewed. Gallstones are definitely associated with certain clinical factors such as pancreatitis, carcinoma of the gallbladder, chronic ileal disease, and obesity. Probable associations have been established for diet, atherosclerosis, hyperlipidemia, diabetes mellitus, peptic ulcer, and gastric surgery. There are two classes of gallstones, cholesterol and bile pigment gallstones. Pigment gallstones may be formed by secretion of an abnormal pigment that readily precipitates in bile, excessive hepatic secretion of a normal pigment that surpasses its solubility in bile, or extrahepatic conversion of a normal constituent into an insoluble precipitate. There are at least six categories of pathophysiologic abnormalities that can lead to abnormal bile and ultimately to cholesterol gallstones: 1) excessive bile salt loss, 2) oversensitive bile acid feedback, 3) excessive cholesterol secretion, 4) rapid bile salt circulation with decreased pool size, 5) a mixed defect that is a combination of types 1 and 2, and 6) primary disorders of the gallbladder, ducts, or sphincters. The definitive treatment of gallstones is surgery, but therapeutic agents are being used (chenodeoxycholic acid, phenobarbital) and actively investigated (lecithin, α-glycerophosphate).

3356 DISTURBANCES IN GASTRIC EMPTYING IN GALLSTONE PATIENTS. (Ger.) Otten, G.; Helwing, E.; Lux, M. (Klinik fur Allgemeinchirurgie, Medizinische Hochschule, Podbielskistrasse 380, D-3000 Hannover 51, W. Germany). *Wien. Med. Wochenschr.* 127(24):741-742; 1977.

Gastric emptying was studied in 35 patients with cholelithiasis during symptom-free intervals. Gastric juice analysis revealed normal values in all cases. Gastric emptying was assessed from the exhalation of radioactive carbon dioxide following the administration of a test meal (low-fat cottage cheese mixed with ^{14}C-labeled glutaminic acid, 15 μCi). The $^{14}CO_2$ exhalation was significantly higher in normal subjects than in the patients with cholelithiasis (4,000-5,000 counts/min versus about 2,000 counts/min, resp.). These changes are interpreted as an expression of disturbances in gastric motor functioning. The findings indicate retarded gastric emptying in patients with cholelithiasis even during asymptomatic intervals.

3357 CHOLELITHIASIS IN CHILDREN AND ADOLESCENTS. (Ger.) Gotz, M.; Granditsch, G.; Helmer, F.; Howanietz, L.; Wagner, I. U. (Universitats-Kinderklinik Wien, Wahringer Gurtel 74-76, A-1090 Vienna, Austria). *Wien. Klin. Wochenschr.* 89(20): 686-690; 1977.

Cholelithiasis was found in 10 children and adolescents (2 boys, 8 girls, aged 11-20 yr) during a 19-yr-period. The length of the anamnesis ranged from 5 days to 6 yr, averaging about 2 yr. The symptoms included abdominal pains and disorders in all cases, tenderness in the right upper quadrant in eight, and jaundice in four. Predisposing conditions were found in five cases: spherocytosis in three and familial cholecystopathy in two. The serum bilirubin level, determined in nine cases, was in the normal range in six. The other laboratory tests were not conclusive. Cholelithiasis was diagnosed by x-raying in six cases, and by oral cholecystography or i.v. cholangiography in the others. Cholecystectomy was performed in all cases; the postoperative course was uneventful in nine cases, one patient developed localized peritonitis. Multiple gallstones and signs of chronic cholecystitis were found in all cases. Cholecystectomy should be performed in all gallstone patients, even in the absence of symptoms.

3358 PROGRESS REPORT: NON-SURGICAL REMOVAL OF COMMON BILE DUCT STONES. (Eng.) Classen, M.; Ossenberg, F. W. (General Hosp. Hamburg-Barmbek, Rubenkamp 148, D 2000 Hamburg 60, W. Germany). *Gut* 18(9):760-769; 1977.

Common bile duct stones that have been overlooked during surgery may be disclosed after operation by cholangiographic follow-up examinations via the T-tube. The T-tube permits probes and snares to be introduced to remove the stones mechanically under radiological or endoscopic control. It also allows the stones to be irrigated with a solvent for cholesterol (cholic acid being commonly used) or with substances that permit them to be fragmented, e.g., heparin. The removal of common bile duct stones has also been performed using endoscopic papillotomy. Of the more than 1,100 endoscopic papillotomies performed for the removal of stones in the common bile duct, 89% were successful. Complications such as pancreatitis, perforation, bleeding, and septic cholangitis were observed in 94/1,107 patients. The risk of septic cholangitis increased with the size and eventual impaction of the common duct stone; the risk of bleeding seemed to be correlated with the length of the incision and the size of the stone. Indications for endoscopic papillotomy are isolated papillary stenosis, common bile duct stones that were overlooked during surgical operations or are newly formed, and stones with symptoms of obstruction in patients at high risk for surgery.

3359 DIFFERENCES IN RENAL EXCRETION BETWEEN GLYCO-, TAUROCONJUGATES, SULFOCONJUGATES AND GLUCURONOCONJUGATES OF BILE ACIDS IN CHOLESTASIS. (Eng.) Back, P.; Gerok, W. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 93-100; 1977.

The renal excretion of bile acids was studied in 109 patients. Bile acid conjugates were separated into three major groups: glyco-, tauroconjugates, sulfoconjugates, and glucuronoconjugates. Within these groups, the six major bile acids occurring in plasma and urine were determined separately. The glyco-, tauroconjugates were excreted into urine up to limit values, which were not surpassed even at high plasma concentrations. Excretion of sulfoconjugates, however, correlated linearly with plasma concentration, making it possible to calculate clearance values for these derivatives, which approximate maximum rates. This finding may also be true for glucuronoconjugates of chenodeoxycholic acid and 3β-hydroxy-5-cholenoic acid, if larger numbers of patients are being investigated. Based on the differences of renal clearances of the different groups of conjugates, it is hypothesized that bile acids enter the urine by diffusion processes only.

3360 LONG-TERM RESULTS OF PAPILLOSTOMY. (Eng.) Stefanini, P.; Carboni, M.; De Bernardinis, G.; Negro, P. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, France, 8-9 June 1976.* (Basel: S. Karger): 206-212; 1977.

A follow-up study was conducted on 577 patients who had had a papillostomy (sphincteroplasty) at least 1 yr before to determine the therapeutic long-term results of the procedure. The indications for surgery had been common duct lithiasis (338), secondary papillitis (193), primary papillitis (34), and chronic pancreatitis (12). The study was conducted by questionnaire and, in 160 cases, by clinical examination also. Good results, i.e., absence of symptoms of pain or dyspepsia relative to the biliary tract or pancreas, were obtained in 97% of the patients. The pathological conditions causing failures (17) were residual or recurrent stones (9 cases), papillary stenosis (6), cholangitis from reflux (1), and chronic recurrent pancreatitis (1). A number of the failures were caused by operating for the wrong indications. However, these mistakes were made 10 yr ago, when the diagnostic methods that today markedly reduce the incidence of wrong indications for operation were not available. It is concluded that papillostomy, performed with the correct indications, can cure the condition for which it is applied.

3361 BILIRUBIN METABOLISM AND JAUNDICE. (Eng.) Robinson, S. H. (Beth Israel Hosp., Boston, MA). *Pathobiol. Annu.* 6:299-316; 1976.

Normal and defective pathways of bilirubin metabolism are reviewed. Hyperbilirubinemia may be caused either by overproduction or impaired excretion of bilirubin. The most common cause of over-production jaundice is an increased rate of hemoglobin catabolism in hemolytic disorders. An increase in the erythropoietic bilirubin fraction occurs under two conditions: 1) with physiologically regulated erythroid hyperplasia and 2) with pathologic ineffective erythropoiesis (destruction of immature erythroid cells in or soon after leaving the marrow). Causes of impaired bilirubin excretion include defects in hepatic uptake, conjugation, secretion, and/or canalicular function, and extrahepatic obstruction. In acute hepatitis and chronic liver disease, multiple defects in bilirubin metabolism and excretion contribute to hyperbilirubinemia. Despite multiple reasons for unconjugated hyperbilirubinemia, a large portion of the serum bilirubin is typically of the conjugated type in patients with acquired liver damage. This finding appears to be a result of the vulnerability to injury of the secretory pathway as well as obstruction of bile radicles by architectural distortion and edema.

3362 PRIMARY AND SECONDARY CHRONICAL ODDITIS. (Eng.) Laurent, J.; Floquet, J.; Guibal, F.; Watrin, B.; Vosse, A. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, France, 8-9 June 1976.* (Basel: S. Karger): 131-136; 1977.

The diagnosis and treatment of chronic odditis is discussed. Odditis is defined as any state of obstruction of the choledocho-Wirsung junction in conjunction with anatomic fiber inflammation of the papilla and Oddi's sphincter. Cases of primary odditis are extremely rare, found in conjunction with pancreatitis or, more frequently, with lithiasis. Clinical observation, pressure tests, and radiography are necessary for diagnosis; the symptoms are presence of biliary pain and, sometimes, presence of jaundice. Pressure tests are mainly carried out during the operation, but duodenoscopy now makes it possible to perform miniaturized pressure tests without surgery. Radiographic indications of odditis are: 1) dilatation of the main biliary duct, 2) absence of evacuation, and 3) absence of Oddi movement. The last sign is the most reliable and can be studied better by using radiocinema than by conventional radiography. Medical treatment is reserved to cases of anorganic Oddi hypertonicity without lithiasis. Surgery should be used only on rare occasions. An elementary dilatation without duodenotomy may frequently be sufficient. Endoscopic sphincterotomy should be reserved to odditis after cholecystectomy with or without choledocholithiasis.

3363 SIGNIFICANCE OF DEBRAY'S TEST (CHOLERETIC MORPHINE TEST) AND SIMULTANEOUS ENZYME TESTS IN THE DIAGNOSIS OF DYSKINESIA OF THE SPHINCTER OF ODDI. (Hun.) Szollosi, G.; Pap, A.; Dobronte, Z.; Varro, V. (I. Belgyogyaszati Klinika, Szegedi Orvostudomanyi Egyetem, Szeged, Hungary). *Orv. Hetil.* 119(3):139-141; 1978.

The diagnostic value of the choleretic morphine test (Debray's test) was studied in 89 patients with dyskinesia of the hypertonic sphincter of Oddi. Fifty-seven patients had undergone cholecystectomy several years previously. The SGOT, gamma-glutamyl transpeptidase (gamma-GT), and serum and urine diastase levels were also determined before and 1-6 hr after the test in 72 patients. Twenty-eight of the 57 cholecystectomized patients were found to be Debray-positive, and 27 were Debray-negative; the test was not evaluable in 2 patients. Positive tests were found in 3 of the 32 noncholecystectomized patients, 2 tests were not evaluable, and the other was negative. The SGOT level increased from 24 to 73 U in the Debray-positive patients 4 hr after the test, but no such increase was seen in the cholecystectomized, Debray-negative patients. The incidence of pathological SGOT changes was 1/26 in the noncholecystectomized Debray-negative patients, 8/21 in the cholecystectomized Debray-negative patients, and 15/25 in the Debray-positive patients. The gamma-GT and serum and urine diastase tests furnished no diagnostically relevant information. The findings indicate that the combination of Debray's test with the SGOT test is more reliable in the diagnosis of dyskinesia of the hypertonic sphincter of Oddi than is Debray's test alone.

3364 TRANSDUODENAL DILATATION OF THE SPHINCTER AND ITS RISKS. (Ger.) Schmidt, H. D.; Brunner, H.; Wendling, P. (Chirurgische Universitatsklinik Mainz, D-65 Mainz, W. Germany). *Wien. Med. Wochenschr.* 127(24):743-744; 1977.

Experience with transduodenal dilatation (bougienage) of the ampulla of Vater in 795 cases is presented. Ten patients developed complications; four had perforation of the choledochus, two had stenosis of the ampulla of Vater, three had pancreatitis, and a small tumor of the ampulla was overlooked in another. There was no postoperative mortality. If difficult probing occurs, the ampulla should always be exposed by laparotomy. The findings indicate that transduodenal dilatation of the ampulla of Vater is a fairly low-risk intervention, if it is performed for the proper indications.

3365 COMPLICATIONS OF SPHINCTEROTOMY. (Eng.) Mercadier, M.; Clot, J. P.; Chigot, J. P.; Hermant, C. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, France, 8-9 June 1976.* (Basel: S. Karger): 196-200; 1977.

Complications of sphincterotomy in 109 cases are considered along with those in several series reported in the literature. The percentage of sphincterotomies in relation to gallstones was 10% and in relation to stones in the common duct was 40%; these figures are lower than those published by previous authors. The most serious postoperative complication was acute pancreatitis. It was responsible for one death (confirmed at autopsy) and possibly for another, giving a maximum mortality rate due to pancreatitis of 1.8%, which is very close to that reported in other series. However, acute pancreatitis represents a relatively rare complication of sphincterotomy and has also been seen after simple cholecystectomy or bilio-intestinal anastomosis. With respect to postoperative morbidity, the following were seen: two abdominal dehiscences, one leakage of bile, one duodenal fistula, and two subphrenic abscesses, none of which could be imputed to the operative procedure. It is concluded that the procedure is associated with neither greater morbidity nor mortality than other operations involving the main bile ducts. Sphincterotomy is an essential procedure, but it should not be carried out on a routine basis.

3366 BENIGN STRICTURES OF THE TERMINAL COMMON BILE DUCT: PATHOLOGICAL AND SURGICAL CONSIDERATIONS. (Eng.) Fernandez-Cruz, L.; Palacin, A.; Pera, C. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, France, 8-9 June 1976.* (Basel: S. Karger): 137-144; 1977.

In an effort to understand the pathological substratum of stenosis to gain greater precision of diagnostic terminology and to better assess the need for sphincterotomy, a histological study was conducted on specimens obtained by operative biopsy after sphincterotomy in 51 patients (44 women and 7 men) and the results compared with preoperative cholangiographic data. The following conditions were observed: 1) alterations of the glandular system (13 cases), 2) diffuse fibrosis (11 cases), 3) alterations of the glands with inflammatory component (10 cases), 4) inflammatory infiltration (11 cases), and 5) pancreatic heterotopia with fibrosis (2 cases). Among the cases of biliary lithiasis studied, choledocholithiasis was present in 68% and lithiasis of the gallbladder in 31.8%. Benign stricture of the terminal common bile duct was diagnosed by preoperative cholangiogram but the lesion type is unidentifiable until after the sphincterotomy has been performed.

3367 THE GALLBLADDER AS BILIARY CONDUIT IN NON-RESECTABLE EXTENSIVE ACALCULOUS EXTRAHEPATIC DUCTAL OBSTRUCTION. (Eng.) Feuchtwanger, M. M. (Dept. Surgery, Ben Gurion Univ., Beersheba, Israel). *Chir. Gastroenterol.* 11(2):243-247; 1977.

GENERAL

3403 GLUTEN-FREE DIET IN DERMATITIS HERPETIFORMIS: I. CLINICAL RESPONSE OF SKIN LESIONS IN 80 PATIENTS. (Eng.) Reunala, T.; Blomqvist, K.; Tarpila, S.; Halme, H.; Kangas, K. (Univ. Central Hosp., Snellmaninkatu 14, SK-00170 Helsinki 17, Finland). *Br. J. Dermatol.* 97(5):473-480; 1977.

The results of therapy with a gluten-free diet (GFD) for dermatitis herpetiformis in 81 patients were compared with those in 49 dermatitis herpetiformis patients on a normal diet. The 81 patients received a GFD for 6 to 36 months. At the end of treatment, the daily requirement of dapsone was significantly lower in patients treated with a GFD than in the 49 patients on a normal diet ($p<0.001$); the mean daily dose in the GFD group was 92 ± 53 mg before treatment and 37 ± 38 mg after treatment, while in the group on the normal diet, the mean daily dose remained practically unaltered and was 87 ± 44 mg at the end of the study. Ninety-three percent of the patients on a GFD were able to reduce the dose of dapsone, whereas only 16% of the patients on a normal diet were able to do this. Complete remissions occurred only in patients on a GFD. Twenty-eight percent of the patients on a GFD were able to stop dapsone completely and were continuously asymptomatic when they observed a strict diet. A response to a GFD was noted on the mean daily requirement of dapsone as soon as the treatment was initiated, although the length of time for an individual response varied. After 1 yr on a GFD, the patients needed an average about 40% and after 3 yr about 20% of the dose required to control skin symptoms at the beginning of the diet. The patients responded to a GFD irrespective of changes found in the jejunal mucosa and irrespective of the presence or absence of histocompatibility locus antigen-B8.

3404 DERMATITIS HERPETIFORMIS: A COMPARATIVE ASSESSMENT OF SKIN AND BOWEL ABNORMALITY. (Eng.) Cooney, T.; Doyle, C. T.; Buckley, D.; Whelton, M. J. (St. Finbarr's Hosp., Cork, Ireland). *J. Clin. Pathol.* 30(10):976-980; 1977.

To determine whether there is a correlation in severity between the lesions of dermatitis herpetiformis in the skin and in the small bowel mucosa, 18 patients with a clinical diagnosis of dermatitis herpetiformis who were being treated with dapsone and were on an unrestricted diet were studied. The diagnosis was confirmed by finding IgA deposits in the dermal papillae of unaffected skin. Dapsone was discontinued, and biopsy of affected skin was carried out when the typical rash reappeared. The biopsy findings were graded according to the severity of the histological changes. Small bowel tissue from each patient was examined and graded by stereo- and routine microscopy. Thirteen specimens were stereo-microscopically abnormal; all 18 showed villous atrophy, either partial or subtotal; and in 13 the interepithelial lymphocyte count was increased. No correlation was found between the histological severity of the skin and the small bowel lesions. The severity of the skin rash in dermatitis herpetiformis is apparently no guide to the degree of small bowel abnormality.

3405 THERAPEUTIC EXPERIENCE WITH IMODIUM® (LOPERAMIDE), A NEW ANTIDIARRHEAL AGENT. (Ger.) Geginat, G.; Palme, G.; Puls, G.; Seufert, O. (Institut fur Radiologie und Strahlenklinik, Krankenhaus Celler Strasse, 3300 Brunswick, W. Germany). *Therapiewoche* 27(47):8592, 8595-8597, 8600-8603; 1977.

Therapeutic trials with loperamide hydrochloride (Imodium), a new antidiarrheal drug acting directly on the intestinal wall, are described. Double-blind cross-over trials were performed in 10 patients with chronic diarrhea. The diarrhea was of undetermined genesis in five cases; chronic ulcerative colitis was diagnosed in three cases, irritable colon and proctitis in one, and diverticulitis in another. Reasec (diphenoxylate hydrochloride + atropine sulfate) was given as a reference drug. The duration of the treatment with the first drug was up to 35 days, after which the patients were switched to the other (unknown) drug upon recurrence of diarrhea. Both drugs were administered in doses of 10 mg/day. Imodium reduced the frequency of defecation and increased the consistency of the feces more effectively than did Reasec. At the end of the treatment, but before the code was broken, seven patients preferred Imodium to Reasec, two preferred the latter, and one was undecided. Side-effects were seen in five patients; there was only one patient who had side-effects exclusively under Imodium therapy. Forty-five patients with radiogenic diarrhea caused by telecobalt irradiation (total focal dose 575-6,000 rads, average 3,454 rads) were treated with Imodium (average dose 4.51 mg/day, total dose 52.53 mg, average length of treatment 12 days). Normalization of the defecation frequency and of the consistency of the feces were achieved in 42 of the 45 patients after 6.4 days of treatment. The hematological and biochemical examinations (SGPT, SGOT, alkaline phosphatase, creatinine, urea nitrogen, erythrocyte count, WBC count and differential blood picture) showed no changes.

3406 LONG-TERM SURVEY OF THE TREATMENT OF DIARRHEA WITH LOPERAMIDE. (Eng.) Mainguet, P.; Fiasse, R.; Turine, J. B. (Avenue J. Delleur 20, B-1170 Brussels, Belgium). *Digestion* 16(1/2): 69-76; 1977.

Long-term efficacy and safety of loperamide and its possible morphine-like effect were studied in 42 outpatients with chronic diarrhea of varying etiology. Individually adapted doses (2-12 mg) were administered for 140-1,159 days. The daily number of bowel movements, the consistency of stools, and the number of capsules used were recorded. In 32 patients, some of the following indices were estimated: ESR, Hb (hemoglobin), RBC, Hc, WBC and its differential count, and serum iron. In 10 patients, the pupil diameters were measured after the subcutaneous injection of 1 ml of naloxone; this test was also performed in 10 subjects following the injection of an isotonic NaCl solution. No significant difference was observed in loperamide consumption between subjects treated for 6 months, 1 yr, and 2 yr. The mean daily stool frequency in all patients dropped from 6 to 2 ($p<0.0001$) during the first year of treatment. In 25 patients treated longer, it decreased from 5.75 to 2 during the first year ($p<0.0001$) and to 2.5 during the second year ($p<0.0001$). In 11 patients treated for more than 2 yr, the daily stool frequency decreased from 6 to 3 during the first year ($p=0.0005$), to 3 in the second year ($p=0.0005$), and to 2.5 in the third year ($p=0.0006$). In patients whose stools were liquid at the beginning of treatment, the stools became "loose" during the first year ($p<0.0001$). In the group treated longer than 2 yr, the stools were "formed" during the first year ($p=0.0006$) and "loose" during the second ($p=0.03$) and the third ($p=0.0005$) years. The treatment was unsuccesful in five patients with chronic diarrhea of unknown etiology. No adverse effects of loperamide were observed, and laboratory tests did not show any drug-related anomalies in blood composition. No significant difference in the pupil diameters was found between patients injected with naloxone or NaCl solution. The studies proved the efficacy and safety of loperamide in the treatment of chronic diarrhea, and no morphine-like effect was observed.

3407 PROSTAGLANDIN-INDUCED DIARRHOEA TREATED WITH LOPERAMIDE OR DIPHENOXYLATE: A DOUBLE-BLIND STUDY. (Eng.) Lange, A. P.; Secher, N. J.; Amery, W. (Odense Sygehus, Odense, Denmark). *Acta Med. Scand.* 202(6):449-454; 1977.

Loperamide was compared double-blind with diphenoxylate and a placebo in 59 women with diarrhea due to prostaglandin administration for mid-trimester abortion. Treatment was started with the intake of two capsules (2 mg loperamide/capsule or 2.5 mg diphenoxylate/capsule) 2 hr before the first i.m. injection of 15(S-)15 methyl prostaglandin $F_{2\alpha}$ (250 μg every 2 hr) and was then adapted individually, i.e., one capsule after each unformed stool, with a maximum of 10 per 24 hr. Both antidiarrheals were significantly more effective than the placebo in preventing diarrhea, and loperamide was found to be more active than diphenoxylate. The number of double-blind capsules taken per 1 ml of injected prostaglandin solution was significantly higher with the placebo than with loperamide ($p=0.05$), but the difference with diphenoxylate was not significant. The amount of drug in milligrams used per 2 ml prostaglandin was significantly higher with diphenoxylate than with loperamide ($p=0.008$). The mean amounts were 3.5 mg with diphenoxylate as compared with 2.3 mg with loperamide, suggesting that the latter is at least 1.5 times more active than the reference substance in this type of diarrhea. The course of abortion, blood pressure, and vital signs, or prostaglandin side-effects other than diarrhea were not affected by either antidiarrheal, nor could any adverse experience be specifically attributed to them.

3408 SURGICAL MANIFESTATIONS OF EOSINOPHILIC GASTROENTERITIS IN THE PEDIATRIC PATIENT. (Eng.) Hoefer, R. A.; Ziegler, M. M.; Koop, C. E.; Schnaufer, L. (Children's Hosp. Philadelphia, 34th and Civic Center Blvd., Philadelphia, PA 19104). *J. Pediatr. Surg.* 12(6):955-962; 1977.

Four cases of eosinophilic gastroenteritis in children are added to the 11 retrieved from a literature review. The inflammation in these cases and in those in the literature was characterized by mature eosinophils predominating a transmural process, which produced pain, obstruction, perforation, bleeding, or fistulae. All levels of the gastrointestinal tract were involved, but the stomach (25.9%) and small bowel (66.7%) lesions were most common. Eosinophilia occurred in 61% of children and allergy in 13%. X-rays demonstrated a diffuse or localized process. Operative intervention was necessary in some cases to exclude tumors or regional enteritis, and at times to extirpate complications of local disease, but conservative therapy was the treatment of choice for this exacerbating-remitting disease.

3409 NECROTIZING ENTEROCOLITIS: CONTROLLED STUDY OF 3 YEARS' EXPERIENCE IN A NEONATAL INTENSIVE CARE UNIT. (Eng.) Bunton, G. L.; Durbin, G. M.; McIntosh, N.; Shaw, D. G.; Taghizadeh, A.; Reynolds, E. O. R.; *et al.* (Univ. Coll. Hosp. and Medical Sch., London, England). *Arch. Dis. Child.* 52(10):772-777; 1977.

To obtain information about possible predisposing factors in necrotizing enterocolitis (NEC), clinical data from 17 infants treated for NEC were compared with those in 51 controls. The incidence of NEC was 0.2% of live births at the University College Hospital during a 3-yr period and 2.7% of those referred from elsewhere. The mean birth weight of the affected infants was 1,832 g (range 878-3,850 g) and mean gestational age, 33 weeks (range 28-40 weeks). The illness was diagnosed at a mean age of 16 days (range 3-33 days). Fourteen infants survived. One infant developed NEC because of a volvulus, and another because of an apparently abnormal arterial supply to a segment of bowel. Birth asphyxia, the use of umbilical catheters, the length of time that these catheters were in place, and complications of catheterization were all significantly more frequent in the infants who developed NEC than in the controls. These findings support the view that hypoxia and ischemia of the gut wall are important in the pathogenesis of NEC.

3410 SKIN LESIONS IN ACQUIRED ZINC DEFICIENCY DUE TO PARENTERAL NUTRITION.

(Eng.) van Vloten, W. A.; Bos, L. P. (Univ. Hosp., Leiden, Netherlands). *Dermatologica* 156(3):175-183; 1978.

Skin lesions seen in 10 patients who received parenteral nutrition during treatment of chronic enteropathy are described. All patients had a lowered serum zinc concentration (2 μM). The skin lesions were similar to those seen in acrodermatitis enteropathica, and occurred on the face (seborrhoic-like lesions), trunk, and groin (vesicular-pustular lesions). After supplementation with zinc sulfate, the skin lesions disappeared completely. A decrease in the serum alkaline phosphatase level can be regarded as a sign of an impending zinc deficiency. Parenteral nutrition should contain a sufficient amount of zinc.

3411 CELLULAR IMMUNITY IN ADULT MARASMUS.

(Eng.) Bistrian, B. R.; Sherman, M.; Blackburn, G. L.; Marshall, R.; Shaw, C. (Cancer Res. Inst., 194 Pilgrim Rd., Boston, MA 02215). *Arch. Intern. Med.* 137(10):1408-1411; 1977.

Studies were carried out in 12 patients with marasmus to determine what deficits in immune function are found when the serum albumin level is maintained and what degree of adult marasmus is necessary to produce immunodeficiency. All patients had recent weight loss to less than 85% of standard weight/height ratio and a serum albumin level of at least 3 g/100 ml. Cellular immune function was assessed by delayed hypersensitivity skin testing to *Candida* and streptokinase-streptodornase; peripheral lymphocyte count; proportion of thymus- and bone marrow-derived lymphocytes; and whole blood and isolated lymphocyte transformation to phytohemagglutinin, pokeweed mitogen, concanavalin A, *Candida*, and streptokinase-streptodornase. Significant impairment of skin test reactivity while *in vitro* responsiveness remained intact was noted in the marasmic patients. No impairment was found in 12 individuals with recent weight loss who remained at a weight greater than the 85% weight/height ratio. In four marasmic individuals in whom weight loss was arrested by nutritional repletion, skin reactivity returned without substantial change in weight. In this type of marasmus, both depleted nutritional status and weight loss must be present for impairment of skin test responsiveness. These findings confirm relative sparing of more vital functions dependent on protein metabolism in adult marasmus compared to the kwashiorkor-like syndrome of hypoalbuminemic malnutrition seen in adults.

3412 H_2-HISTAMINE RECEPTOR BLOCKING AGENTS IN THE ZOLLINGER-ELLISON SYNDROME: EXPERIENCE IN SEVEN CASES AND IMPLICATIONS FOR LONG-TERM THERAPY.

(Eng.) McCarthy, D. M.; Olinger, E. J.; May, R. J.; Long, B. W.; Gardner, J. D. (Natl. Inst. Arthritis, Metabolism and Digestive Diseases, Bldg. 10, Rm. 9D-17, Natl. Inst. Health, Bethesda, MD 20014). *Ann. Intern. Med.* 87(6):668-675; 1977.

The value of metiamide and cimetidine in the management of the Zollinger-Ellison syndrome was assessed in seven patients with this syndrome (serum gastrin >300 μg/ml, basal acid output >15 mEq/hr, ratio of basal acid output to maximal acid output >0.5). The i.v. or p.o. administration of the drugs lowered acid secretion by at least 70% in all cases. Subsequent treatment of six patients for 3 to 15 months (p.o. therapy) and one patient for 1 month (i.v. therapy) showed that the drugs abolished symptoms in all seven, abolished diarrhea in five, allowed ulcer healing in six, and were well tolerated without adverse effects in all seven. No patient failed to respond to the drug, although one died from tumor progression and two required total gastrectomy for complex reasons. The results indicate that patients with Zollinger-Ellison syndrome can be managed medically and, in light of current mortality trends, gain little from the extra risks attending total gastrectomy.

3413 USE OF CALCIUM AND SECRETIN IN THE DIAGNOSIS OF GASTRINOMA (ZOLLINGER-ELLISON SYNDROME).

(Eng.) Deveney, C. W.; Deveney, K. S.; Jaffe, B. M.; Jones, R. S.; Way, L. W. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Ann. Intern. Med.* 87(6):680-686; 1977.

To delineate the role of calcium and secretin tests in the diagnosis of gastrinoma, 65 patients with peptic ulcer disease were evaluated for gastrinoma (Zollinger-Ellison syndrome) by measuring changes in serum gastrin concentration after the i.v. administration of calcium or secretin, or both. The presence of gastrinoma was established in all 20 patients whose serum gastrin increased by 395 pg/ml or more after i.v. calcium (4 mg/kg/hr, 3 hr) and in all 18 patients whose serum gastrin concentration increased by 110 pg/ml or more after i.v. secretin (2 U/kg). The experience with these patients shows that stimulation by calcium or secretin may confirm the presence of gastrinoma in cases where the diagnosis would otherwise remain obscure. Although a positive response to calcium or secretin is diagnostic for gastrinoma, a negative response does not exclude this diagnosis. Stimulation with secretin is preferred for screening for gastrinoma because it is quicker and more reliable than calcium.

3414 HISTOCOMPATIBILITY ANTIGENS (HL-A) IN COW'S MILK INTOLERANCE WITH MALABSORPTION SYNDROME IN CHILDREN [Abstract]. (Eng.) Kuitunen, P.; Tiilikainen, A.; Visakorpi, J. K. (No affiliation given). *Acta Paediatr. Belg.* 29(2):126; 1976.

GENERAL

Parasitology

3454 HEPATIC AMEBIASIS--ANALYSIS OF 56 CASES. II. LABORATORY AND CHEST X-RAY FINDINGS. (Eng.) Carneiro Chaves, F. J. Z.; Cruz, I.; Gomes, C.; Domingues, W.; Marques da Silva, E.; Tavarela Veloso, F. (Hosp. de S. Joao, Porto, Portugal). *Am. J. Gastroenterol.* 68(3):273-277; 1977.

Laboratory and chest x-ray findings are reviewed in 56 previously reported patients with hepatic amebiasis. Anemia and an elevated ESR, frequently without an elevated WBC count, were the most frequent hematologic findings; anemia occurred in 60.7% of patients, and an elevated ESR was found in 92.9%. Abnormalities of liver function tests were mild and nonspecific. The most frequent abnormality seen in the chest x-ray was an elevated right hemidiaphragm (74.5% of 55 patients x-rayed). The motility of the hemidiaphragm on fluoroscopy was reduced or abolished in 24 of 36 cases. These abnormalities may be useful in the diagnosis of amebiasis in endemic areas where more sophisticated facilities may not be available.

3455 A COMPARISON OF A SHORT COURSE OF SINGLE DAILY DOSAGE THERAPY OF TINIDAZOLE WITH METRONIDAZOLE IN INTESTINAL AMOEBIASIS. (Eng.) Misra, N. P.; Gupta, R. C. (Gandhi Medical Coll., Bhopal, India). *J. Int. Med. Res.* 5(6):434-437; 1977.

The therapeutic value of tinidazole was compared with that of metronidazole in 60 patients with symptomatic intestinal amebiasis who were treated for 3 days with a single dose of 2 g of either drug, resp., by random order. Tinidazole cured 27/30 patients and metronidazole cured 16/30 patients ($p<0.01$). Mild side-effects were reported by 8/30 patients in the tinidazole group as compared to mild to moderate side-effects reported by 16/30 patients in the metronidazole group ($p<0.05$). As the average patient has only a limited understanding and toleration of extended treatment courses, the advantages of a short course employing a single daily dose are obvious. With such a regimen, tinidazole is superior to metronidazole in the treatment of intestinal amebiasis.

3456 TREATMENT OF HEPATIC HYDATID DISEASE WITH MEBENDAZOLE: PRELIMINARY RESULTS IN FOUR CASES. (Eng.) Bekhti, A.; Schaaps, J. P.; Capron, M.; Dessaint, J. P.; Santoro, F.; Capron, A. (Baviere Hosp., 4020 Liege, Belgium). *Br. Med. J.* 2(6094):1047-1051; 1977.

Clinical echotomographic and serological investigations were carried out in four patients who received mebendazole for the treatment of hepatic hydatid disease. In three patients, hydatidosis had remained after surgery, and in the fourth it could not be treated surgically. Mebendazole was given p.o. in maximum doses of 400-600 mg three times a day during courses lasting 21 to 30 days. Ultrasonic echotomography showed a complete regression of the intrahepatic cysts after 4 to 13 months in all four cases. In three patients, the course of treatment had to be repeated. Mebendazole also induced clinical improvement and a progressive lowering of the concentration of specific IgE of *Echinococcus granulosus*. During treatment, circulating blood levels of specific immune complexes of antigen 5 were increased. These observations indicate that mebendazole has a lethal effect on *E. granulosus* cysts in primary hydatid disease in man and that the efficacy of chemotherapy can be assessed with ultrasonography and by measuring changes in the concentration of specific IgE of *E. granulosus* and circulating immune complexes.

3457 GIARDIASIS IN DAY-CARE CENTERS: EVIDENCE OF PERSON-TO-PERSON TRANSMISSION. (Eng.) Black, R. E.; Dykes, A. C.; Sinclair, S. P.; Wells, J. G. (Center for Disease Control, Atlanta, GA 30333). *Pediatrics* 60(4):486-491; 1977.

An outbreak of diarrhea that occurred in children 1 to 3.5 yr old attending a day-care center during August and September 1975 was investigated. There were overlapping epidemics of shigellosis and giardiasis, with 54% of the children infected with *Giardia lamblia*. At two other centers, 29% and 38% of the children had *G. lamblia* infection, but none had *Shigella*. The prevalence of *G. lamblia* in the day-care children was significantly higher than the 2% prevalence in age-matched children not in day-care centers. The fact that the highest infection rate was found in mobile 1-yr-olds who were not toilet-trained suggests fecal-oral transmission of the parasite from child to child in the centers and from infected children to other family members.

3458 A COMMUNITYWIDE OUTBREAK OF GIARDIASIS WITH EVIDENCE OF TRANSMISSION BY A MUNICIPAL WATER SUPPLY. (Eng.) Shaw, P. K.; Brodsky, R. E.; Lyman, D. O.; Wood, B. T.; Hibler, C. P.; Healy, G. R.; *et al.* (Center for Disease Control, Atlanta, GA 30333). *Ann. Intern. Med.* 87(4):426-432; 1977.

An epidemiologic investigation was undertaken when 350 residents of Rome, New York, developed laboratory-confirmed cases of giardiasis between 1 November 1974 and 7 June 1975. A random household survey showed an overall attack rate for giardiasis (defined as a diarrheal illness of ≥5 days duration) of 10.6%. A significant association was discovered between having giardiasis and using city water and between having illness and drinking one or more glasses of water a day. The presence of human settlements in the Rome watershed area suggested that the water supply could have been contaminated by untreated human waste. The infectivity of municipal water was confirmed by producing giardiasis in specific pathogen-free dogs fed sediment samples of raw water obtained from an inlet of a city reservoir. A microscopic examination of the water sediments uncovered a *Giardia lamblia* cyst in one sample. This was the first time that a *G. lamblia* cyst has been found in municipal water in an epidemic and the first time that such water has been shown to infect laboratory animals.

3459 GIARDIASIS WITH TOTAL VILLOUS ATROPHY. (Eng.) Levinson, J. D.; Nastro, L. J. (55 Morris Ave., Springfield, NJ 07081). *Gastroenterology* 74(2, Part 1):271-275; 1978.

The case of a patient who developed symptomatic giardiasis with total villous atrophy after a tour of the Soviet Union is presented. The patient, a 57-yr-old woman, presented with a 2-week history of diarrhea and abdominal distention. Giardiasis was diagnosed by duodenal aspiration. A small intestinal biopsy revealed total villous atrophy in the absence of celiac sprue or a gastrointestinal immunodeficiency syndrome, a finding not previously described. The biopsy remains normal after a single course of metronidazole (250 mg, t.i.d., 10 days), despite subsequent exposure to gluten.

3460 ACUTE PERFORATING AMEBIC COLITIS. (Por.) Kerzner, A.; De Almeida Magalhaes, A.; Mattosinho Franca, L. C. (Hospital Sao Joaquim da Real e Benemerita Sociedade Portuguesa de Beneficencia de Sao Paulo, Sao Paulo, Brazil). *An. Paul. Med. Cir.* 104(1):57-69; 1977.

3461 HYDATID DISEASE: EPIDEMIOLOGY, DIAGNOSIS, AND THERAPY. (Ger.) Bahr, R.; Koslowski, L. (Chirurgische Universitatsklinik, Calwer Strasse 7, 7400 Tubingen, W. Germany). *Dtsch. Med. Wochenschr.* 102(30):1098-1101; 1977.

GENERAL

Regional Enteritis

3462 HISTOCHEMICAL COMPARISON OF THE EPITHELIAL MUCINS IN THE ILEUM IN CROHN'S DISEASE AND IN NORMAL CONTROLS. (Eng.) Culling, C. F. A.; Reid, P. E.; Dunn, W. L.; Clay, M. G. (Dept. Pathology, Univ. British Columbia, Vancouver V6T IW5, Canada). *J. Clin. Pathol.* 30(11):1063-1067; 1977.

Epithelial mucins were studied using routine and special histochemical methods in specimens of small intestine from patients with Crohn's disease and from normal controls. The normal ileal goblet cells were found to secrete a predominantly nonsulfated sialomucin. The neuraminidase insensitivity of the sialic acids of the small intestine was not due to either O-acylation at C_4 or an ester substituent at C_1. This finding implies that the protection against enzyme attack afforded to the mucosa by the mucin coat in the small intestine utilizes a different mechanism from that in the colon. Although, in many respects, the small intestinal mucins in Crohn's disease patients and in normal controls were similar, there was an increase in side-chain O-acylated sialic acids in such mucins in Crohn's disease. This difference has not been described before, probably because it can be seen only after staining such sections by the periodate-thionin Schiff/saponification/PAS and periodate-borohydride technique/saponification/PAS.

3463 CANCER IN CROHN'S DISEASE AFTER DIVERSIONARY SURGERY: A REPORT OF SEVEN CARCINOMAS OCCURRING IN EXCLUDED BOWEL. (Eng.) Greenstein, A. J.; Sachar, D.; Pucillo, A.; Kreel, I.; Geller, S.; Janowitz, H. D.; *et al.* (Mount Sinai Sch. Medicine, Fifth Ave. and 100th St., New York, NY 10029). *Am. J. Surg.* 135(1):86-90; 1978.

The incidence of bowel cancer was studied in 132 patients who had undergone bypass surgery for Crohn's disease and who had been admitted to one hospital between 1960 and 1976. Seven patients developed cancer (4/63 with ileocolitis and 3/69 with ileitis). All seven cancers appeared in excluded loops, four in small bowel and three in colon. Six cancers occurred at sites of previous active inflammatory disease and one in a relatively normal "skipped" area of cecum. Four were associated with fistulas, two with enterovesical, one with enterocutaneous, and one with both. In only one case was a tumor mass palpable. All seven patients in this series underwent operation, and all showed metastatic spread to liver, lymph nodes, or adjacent organs. All patients died within 2 yr following the diagnostic laparotomy. The mean latent period between onset of disease and appearance of cancer was 27 yr and between bypass surgery and appearance of cancer 13 yr. Four of the seven cancers occurred relatively early, within 4 yr of the bypass procedure, but all seven cases had one feature in common--a long duration of Crohn's disease (ranging from 17 to 44 yr) prior to the development of cancer. The diagnosis of cancer in excluded bowel was difficult to make and impossible to confirm prior to laparotomy. Among the large bowel cancers, a preoperative diagnosis was established by sigmoidoscopy in only one case. Cancer in a bypassed loop should be suspected in any case of Crohn's disease of long duration when a late recrudescence of symptoms occurs, especially when the symptoms are associated with the new appearance of fistula or mass.

3464 GALLSTONE PREVALENCE AND BILIARY LIPID COMPOSITION IN INFLAMMATORY BOWEL DISEASE. (Eng.) Marks, J. W.; Conley, D. R.; Capretta, T. L.; Bonorris, G. G.; Chung, A.; Coyne, M. J.; *et al.* (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *Am. J. Dig. Dis.* 22(12):1097-1100; 1977.

Biliary cholesterol saturation was correlated with disease variables that might affect bile acid loss in nine ileitis patients with intestinal resection and eight ileitis patients without intestinal resection having a defined prevalence of gallstones. In addition, cholesterol saturation was determined in 7 ulcerative colitis patients, 18 gallstone patients, and 5 normal controls. The biliary cholesterol saturation index in ileitis patients both with and without resection (2.34 ± 0.14 and 2.07 ± 0.09, resp.) was similar to that in gallstone patients (2.10 ± 0.05), yet the prevalence of gallstones was only 12%. Cholesterol saturation did not correlate with ileal resection or the extent, duration, or activity of ileitis. Biliary cholesterol saturation was not different in ulcerative colitis patients from that in normal subjects. It is concluded that cholesterol saturation of bile alone does not account for the high prevalence of cholesterol gallstones that has been reported in ileitis patients.

3465 PATHOGENESIS OF DIVERTICULITIS COMPLICATING GRANULOMATOUS COLITIS. (Eng.) Meyers, M. A.; Alonso, D. R.; Morson, B. C.; Bartram, C. (New York Hosp., 525 E. 68 St., New York, NY 10021). *Gastroenterology* 74(1):24-31; 1978.

The pathological and radiological features of diverticulitis complicating granulomatous colitis were correlated with granulomatous colitis and associated diverticula in 21 patients who underwent resection during a 14-yr period. Sigmoid diverticulitis was pathologically confirmed in 10 patients. The radiological signs of peridiverticulitis complicating granulomatous colitis usually showed clear evidence of the underlying pathological changes. They included localized diverticular perforation, sometimes with multiple communications via a paracolonic sinus tract, mass pressure from the paracolic abscess, and occasionally some degree of communication with deep fissuring ulcers of Crohn's disease. Because diverticula breach the colonic wall, histological analysis confirms that their involvement by the transmural process of granulomatous colitis predisposes to peridiverticulitis and/or abscess formation.

3466 APHTHOID ULCERS IN CROHN'S COLITIS. (Eng.) Simpkins, K. C. (General Infirmary, Leeds, England). *Clin. Radiol.* 28(6):601-608; 1977.

One hundred and nine double-contrast barium enema examinations were carried out in 91 adults with Crohn's colitis, and the radiographs were examined for the presence of aphthoid ulcers. These small discrete ulcers were found in 40 patients and in 48 of the 109 examinations. Seen *en face*, each ulcer appeared as a central fleck of barium surrounded by a translucent halo set amid a patch of normal mucosa. Their detection gave a more accurate assessment of the extent of disease. The radiographic demonstration of the evolution of ulceration is illustrated; it closely reflected what was seen on macroscopic examination of excised specimens and explains the characteristic patchiness and discontinuity of disease.

3467 HOME PARENTERAL NUTRITION AS PRIMARY THERAPY IN PATIENTS WITH EXTENSIVE CROHN'S DISEASE OF THE SMALL BOWEL AND MALNUTRITION. (Eng.) Fleming, C. R.; McGill, D. G.; Berkner, S. (Mayo Clinic, 200 First St. SW, Rochester, MN 55901). *Gastroenterology* 73(5):1077-1081; 1977.

Experience with seven patients with extensive Crohn's disease who had received nightly supplementary home parenteral nutrition (HPN) for a total of 120 patient months is presented. Indications for HPN were short bowel in five patients, growth failure in one, and gastric outlet obstruction in one. Before HPN, body weight averaged 72% of ideal body weight in five patients; one adolescent was less than the third percentile in weight. Anthropometry in six patients confirmed the decrease in fat and lean body mass in all. All patients were anemic, and serum albumin was low in six of seven (1.8-3.0 g/dl). During HPN, the average weight gain was 11 kg in the six patients treated for 6 months or longer. Hemoglobin increased an average of 1.5 g/dl and serum albumin increased an average of 1.0 g/dl. There was 50% fewer hospitalizations after HPN was begun compared with similar time periods before HPN. HPN did not prevent or reverse complications of Crohn's disease other than malnutrition. Major complications were displacement of the catheter on two occasions in one patient and metabolic acidosis in two patients. Sepsis did not occur. HPN is justified in selected patients with extensive Crohn's disease and malnutrition in that patients gain weight, nutritional parameters improve, and patients' activities increase as the number of hospitalizations decrease.

3468 CROHN'S DISEASE: CLINICAL AND THERAPEUTIC EXPERIENCE. (Spa.) Serrano Sanchez, P. A.; Martinez-Pineiro Carames, M.; Perez-Bedmar Pelaez, J. A.; Miras Estacio, M. (Gran Hospital del Estado, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 50(4):391-408; 1977.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

3470 NAFENOPIN-INDUCED PROLIFERATION OF PEROXISOMES IN THE SMALL INTESTINE OF MICE. (Eng.) Psenicnik, M.; Pipan, N. (Medical Faculty Univ., Yu-6100 Ljubljana, Lipiceva 2, Yugoslavia). *Virchows Arch.* [*Cell Pathol.*] 25(2): 161-169; 1977.

The effect of nafenopin on the epithelial cells of the small intestine was studied in male Albany mice to determine whether the peroxisomal response to the hypolipidemic drug and the accompanying hypolipidemic effects seen in hepatocytes also occur in other tissues. The mice were fed white bread to which nafenopin was added to provide a daily dose of 1.25 g/kg, and, after 17 days, the control and nafenopin-treated groups were sacrificed. The tissues were incubated in alkaline DAB medium. Ultrathin sections of small intestinal tissue were examined by electron microscopy, and morphological differences in the peroxisomes and mitochondria between the controls and the experimental group were quantitated. In the nafenopin-treated group, proliferation of peroxisomes occurred, as indicated by significant increases in volume, surface, and numerical density of these structures compared with controls. No such alterations were found in the mitochondria. These results show that the response of small intestinal epithelial cells to nafenopin is analogous to that produced in hepatocytes by the same drug. Hepatocyte peroxisomes are supposed to be involved in lipid metabolism, and it seems that small intestinal epithelial peroxisomes play a similar role.

3471 VASCULARIZATION OF THE MYENTERIC PLEXUS IN THE SMALL INTESTINE OF THE HOG AND CAT. (Ger.) Stach, W. (Anatomisches Institut des Bereichs Medizin, Wilhelm-Pieck-Universitat, Gertrudenstrasse 9, DDR-25 Rostock, E. Germany). *Acta Anat. (Basel)* 100(1):161-169; 1978.

The anatomy of the vascularization of the myenteric plexus of the small intestine was studied in 3- to 6-week-old piglets and 16- to 20-week-old cats. The ganglia of the myenteric plexus were found to have independent vascularization in the form of periganglionic capillary networks. As to architecture and density, these capillaries are quite different from the intramuscular capillary bed. The terminal arterioles and sphincteric capillaries running into the periganglionic capillary network are innervated by noradrenergic axons as are the arterial trunk and arcade vessels. Together with the periganglionic arteriovenous shunts, this architecture represents favorable prerequisites for a functionally adapted blood supply to the ganglia. The specific arrangement of intramuscular vessels and the myenteric plexus provides for the close topographic and functional relations between the two systems in all cases of change in the shape of the intestinal wall (e.g., contraction, relaxation, and filling).

3472 LYMPHOID FOLLICULAR PATTERN: A NORMAL FEATURE OF THE PEDIATRIC COLON. (Eng.) Laufer, I.; deSa, D. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Am. J. Roentgenol.* 130(1):51-55; 1978.

The lymphoid follicular pattern of the colon was examined in 27 patients less than 15 yr old who underwent double contrast enema. Tiny nodular filling defects up to 2 mm in diameter were seen in 12 of these 27 patients. This pattern was particularly common in children under 5 yr of age; filling defects were demonstrated in seven of nine such patients in whom a good double contrast study was achieved. Among 12 patients with diarrhea and/ or rectal bleeding, 10 had lymphoid hyperplasia. However, 5 of 15 patients in whom the condition was not demonstrated had the same symptoms. Only one patient, a girl with juvenile polyposis, underwent subsequent hospitalization. Subtotal colectomy was performed because of chronic malnutrition and failure to thrive. In all other patients, the final radiologic diagnosis was a normal colon with lymphoid hyperplasia. Although the above lymphoid follicular pattern of the colon has been termed lymphoid hyperplasia, it is suggested that it represents a normal lymphoid follicular pattern in the pediatric colon. The term lymphoid hyperplasia should be reserved for cases in which the lymphoid follicles are greater than 2 mm in diameter; this will usually represent an abnormal condition in response to infection, allergy, or immunologic disorders. Several conditions may have a radiographic appearance that resembles the lymphoid follicular pattern described above. Occasionally, particularly when familial polyposis is discovered in a young patient, the appearance of it may resemble lymphoid hyperplasia. In such cases, removal of a rectal polyp for histologic examination will establish the diagnosis. True lymphoid hyperplasia is one of the pathologic features of Crohn's disease, and it is not surprising that, in the early stages, mucosal modularity identical to the lymphoid follicular pattern can be seen. However, the patients described here tend to be older, and more advanced disease elsewhere in the gastrointestinal tract usually will provide the clue to the correct diagnosis.

3473 FLUORESCENCE STAINING OF GASTRIC MUCOSA. A STUDY WITH SPECIAL REFERENCE TO PARIETAL CELLS. (Eng.) Stave, R.; Brandtzaeg, P. (Natl. Hosp. Norway, Oslo, Norway). *Scand. J. Gastroenterol.* 12(7):885-891; 1977.

Precise and simple methods for enumeration of parietal cells alone or in combination with other cell types by paired staining were developed. Resected stomachs from patients with partial gastric resection were fixed at 4 C with either paraformaldehyde or 1-ethyl-3(3 dimethyl-amino-propyl)carbodiimide

HCl (CDI). After 24 hr in CDI, small specimens were dehydrated and paraffin embedded. Pieces of rat gastric mucosa were either processed as above or by alcohol fixation and then paraffin embedded. Other pieces were embedded fresh in Cryoform and frozen. Sera from two individuals with high parietal cell antibody titers (1:512) were used as the source of IgG to obtain fluorescein and rhodamine conjugates. Gastrin (G) cells were demonstrated by direct immunofluorescence, whereas parietal cells were demonstrated either directly or indirectly. Staining methods included the use of hematoxylin and eosin with saffron (HES) or hematoxylin, azophloxine, and saffron (HAS). Other sections were stained with PAS followed by eosin at various concentrations. The number of parietal cells in a standardized area unit was counted. Fluorescence visualization of parietal cells using both HES and HAS staining was superior to conventional light microscopy. It enabled recognition of parietal cells in the gastric body mucosa at low magnification. The HES and HAS methods did not satisfactorily visualize antrum parietal cells. The PAS-eosin method successfully demonstrated antrum parietal cells because of the contrasting red background of the pyloric glands. Paired visualization of parietal and G cells in the same tissue section was achieved immunohistochemically. This methodology is a prerequisite for detailed studies of these two cell types in the transitional zone between the gastric body and the pyloric antrum.

3474 PHALLOIDIN INHIBITS THE FORMATION OF A FILAMENTOUS WEB SURROUNDING ENDOCYTOTIC VACUOLES IN LIVER PARENCHYMAL CELLS. (Ger.) Jahn, W. (Abteilung Naturstoff-Chemie, Max-Planck-Institut fur medizinische Forschung, Heidelberg, W. Germany). *Cytobiologie* 15(3):452-462; 1977.

The effect of pretreatment of the isolated rat liver with phalloidin (1.5 mg) 15-20 min before perfusion at increased posthepatic pressure (15 cm of water column) on the formation of a filamentous web around endocytotic vacuoles was studied. Liver perfusion alone caused the formation of endocytotic vacuoles in the liver parenchymal cells, and most of the vacuoles were surrounded by a filamentous web. Small secondary vacuoles were formed during the spontaneous diminution of the vacuolization. The secondary vacuoles, formed from the primary ones, were found exclusively near by well-marked filamentous areas. Pretreatment of the liver with phalloidin prior to perfusion inhibited the formation of the filamentous web around the endocytotic vacuoles. Clusters of small vacuoles, seen after perfusion without phalloidin pretreatment, were not observed after pretreatment. The inhibiting effect of phalloidin on the formation of the filamentous web is most probably due to the fact that the filamentous web consists of F-actin polymerized from G-actin, with phalloidin causing the transformation of the entire G-actin into F-actin that is no longer available for the formation of the filamentous web. The filamentous web may participate in the release of water due to its contractile action.

3475 REGIONAL VARIATIONS IN ELECTROLYTE CONTENT OF SMOOTH MUSCLE OF OPOSSUM ESOPHAGUS: EFFECTS OF INHIBITION OF Na^+-K^+ ATPase [Abstract]. (Eng.) Schulze, K.; Hajjar, J. J.; Christensen, J.; Miller, S. (Univ. Iowa Coll. Medicine, Iowa City, IA 52242). *Fed. Proc.* 36(3):462; 1977.

3476 VENOUS ANGIOARCHITECTURE OF THE TUNICA MUSCULARIS IN THE ESOPHAGOGASTRIC TRANSITION SEGMENT IN MAN. (Eng.) Fujimura, I.; Ferraz de Carvalho, C. A. (Dept. Anatomy, Univ. San Paulo, Av. Dr. Arnaldo, 455, Sao Paulo, Brazil). *Acta Anat. (Basel)* 98(4):401-412; 1977.

3477 COMPARATIVE ULTRASTRUCTURE OF THE SURFACE EPITHELIUM OF STOMACH AND ESOPHAGUS [Abstract]. (Eng.) Friedman, M. H. F.; Marchant, L. M. (Philadelphia Coll. Osteopathic Medicine, Philadelphia, PA). *Gastroenterology* 72(5, Part 2):1059; 1977.

3483 TRANSPORT OF FAT THROUGH JEJUNAL ABSORPTIVE EPITHELIUM IN VITRO.

(Eng.) Mohiuddin, A.; Ahmed, M. M.; Chan, H. L. (Univ. Riyadh, Riyadh, Saudia Arabia). *Acta Anat.* 100(4):435-440; 1978.

The transport of fat through jejunal absorptive epithelium *in vitro* was studied in the white rat to determine the functional role of the infranuclear cytoplasm of the epithelial cells. The mucosa of excised pieces of jejunum from fasting rats was exposed for 10 min to fresh chyme obtained from other rats that had been digesting either buttered bread or bread alone and was then processed for electron microscopy. After exposure to fatty chyme, very fine lipid globules were seen between microvilli; larger globules were found in the supranuclear cytoplasm of all epithelial cells and in the infranuclear cytoplasm of some. The globules were found tightly bunched in supranuclear Golgi apparatus, and smaller collections were found in the infranuclear Golgi apparatus of some cells. Globules of an intermediate size were scattered more evenly in the cytoplasm both above and below the level of the nucleus. Occasional lymphatics in the villus core contained fat globules. Vesicles of little density were contained throughout the cells. But the most notable feature was the large collection of finely granular deposit in the deepest part of the infranuclear region between the mitochondria and endoplasmic reticulum above and the plasmalemma resting on the basement membrane below. These collections caused considerable elongation of the cells toward the lamina propria, and appeared to be nonlipid material conveyed there for clearance through the cell but not yet expelled due to the absence of blood flow through the villus. After exposure to chyme that did not contain fat, no globules of fat were seen in the epithelial cells or the lamina propria, but the low-density vesicles were more numerous in the cytoplasm, and the basal parts of the cells contained an even larger collection of finely granular nonlipid material than in the experiment with fatty chyme. The results support the hypothesis that infranuclear cytoplasm of absorptive epithelial cells takes part in the transport of absorbed fat, whose globules are collected in the infranuclear and supranuclear Golgi apparatus, but the possibility still exists that absorbed fat may leave through the sides of cells without reaching the bases.

3484 IDENTIFICATION OF KETONE BODIES AND GLUTAMINE AS THE MAJOR RESPIRATORY FUELS IN VIVO FOR POSTABSORPTIVE RAT SMALL INTESTINE.

(Eng.) Windmueller, H. G.; Spaeth, A. E. (Natl. Inst. Health, Bethesda, MD 20014). *J. Biol. Chem.* 253 (1):69-76; 1978.

The *in vivo* metabolism of circulating substrates was studied quantitatively in rat jejunal segments with an intact arterial supply and totally collected venous drainage. Net uptake or release of various blood metabolites was measured chemically, and the steady state rates of metabolism of arterial substrates to venous products were measured radiochemically. The major carbon sources taken up were glutamine, acetoacetate, 3-hydroxybutyrate, and glucose. Net uptake of each was in the range of 160 to 220 nmol/min/g intestine, which was equivalent to 30% of the circulating flux through the tissue for glutamine, 10% to 15% for the ketone bodies, and 2% for glucose. Plasma unesterified fatty acids were poorly utilized, less than 1% of the flux being taken up. Glutamine carbon was the source for about 35% of the CO_2 produced and ketone bodies for an additional 50%. The remaining CO_2 was derived from glucose (7%), lactate (5%), and unesterified fatty acids (3%). Additional end products for glutamine and ketone body carbon included lactate and, to a smaller extent, glucose. Glucose carbon atoms taken up were largely recovered as lactate and alanine, suggesting weak pyruvate dehydrogenase activity. Although the jejunum produced lactate, it also metabolized about 10% of the circulating lactate flux through the tissue, mostly to alanine. Half of the carbon of alanine released by jejunum was derived from blood lactate and the rest from the other metabolized substrates. Lactate uptake exceeded release when blood concentrations exceeded 1.2 to 1.6 mM. Nitrogenous end products of glutamine metabolism included NH_3 and alanine, and smaller amounts of ornithine, citrulline, and proline. These results identify ketone bodies and glutamine as the major respiratory fuels in postabsorptive small intestine *in vivo* and provide additional details regarding intermediary metabolism in this tissue.

3485 EFFECT OF TRANSIENT INTESTINAL ISCHAEMIA ON THE THORACIC DUCT LYMPH ABSORPTION OF ENDOTOXIN.

(Eng.) Nozickova, M.; Bartos, V.; Sedlak, J. (Inst. Clinical and Experimental Medicine, Budejovicka 800, 146 22 Praha 4, Czechoslovakia). *Lymphology* 10(3):161-165; 1977.

Changes of the thoracic duct lymph flow and composition attending intestinal ischemia and following intestinal revascularization were studied in eight mongrel dogs to assess the role of lymph vessels for the transport of toxic substances produced by or resorbed from the ischemic intestine. One-hour intestinal ischemia was produced by clamping the superior mesenteric artery and interrupting the intramural collaterals; revascularization was followed for 4 hr. Intestinal ischemia was associated with a decrease ($p<0.01$) in thoracic duct lymph flow, an increase in lymph/plasma ratio for total protein ($p<0.05$), and a rapid increase in the lactic acid level only in the blood of mesenteric vein ($p<0.01$). Lactic acid level remained elevated ($p<0.01$) in mesenteric venous blood and became elevated in the lymph ($p<0.01$) and arterial blood ($p<0.05$) during revascularization. LDH activity increased in mesenteric venous blood during ischemia and remained elevated during revascularization ($p<0.01$); in the lymph and in arterial blood, LDH levels rose ($p<0.01$ and $p<0.05$, resp.) during revascularization. The lymph/plasma ratio for total protein decreased significantly ($p<0.05$) after 1 hr of revascularization, and the thoracic duct lymph hematocrit was significantly ($p<0.01$)

elevated between 0.5 and 2 hr of revascularization. Using the limulus test, endotoxin activity was found in the lymph of four of six dogs and in the mesenteric vein blood in one dog before intestinal ischemia but was absent in arterial blood. After the 1 hr of ischemia, endotoxin was present in the lymph of all six dogs and in the venous blood of one. After 1 hr of revascularization, endotoxin was present in the thoracic duct lymph of six dogs, intestinal venous blood of four dogs and arterial blood of three dogs. It is concluded that during intestinal ischemia lymph transport from the gut is low but may be sufficient for the transport of endotoxin. Transport via the intestinal lymph significantly increases after revascularization, and limulus-positive substances escape from the ischemic intestine both via the lymph and blood.

3486 QUANTITATIVE RELATIONS BETWEEN THE MONOSACCHARIDE-INDUCED CHANGE OF ION TRANSPORT AND MONOSACCHARIDE ACCUMULATION IN THE RAT JEJUNUM. (Ger.) Remke, H.; Muhle, W.; Mothes, T.; Muller, F. (Physiologisch-Chemisches Institut, Karl-Marx-Universitat, 701 Leipzig, E. Germany). *Acta Biol. Med. Ger.* 36(7):7-15; 1977.

The changes induced by the Na^+-dependent transport of monosaccharides (10 mM) in the unidirectional influx of Na^+ and K^+ ions through the microvillous membrane (brush border) were studied in *in vitro* preparations of the rat jejunum. The monosaccharide-induced change in the Na^+ and K^+ influx was found to be a function of the ion gradients at the brush border. The monosaccharide-induced change in the permeability of the brush border also caused a decrease in the K^+ concentration and an increase in the Na^+ concentration during the energy-dependent accumulation of the monosaccharide. The monosaccharide concentration in the tissue reached an end value that was proportional to the change in the Na^+ and K^+ influx and to the change in the ion concentration; this end value remained unchanged even when the Na^+ gradient was eliminated and the intracellular K^+ concentration was low. The correlation between the elimination of the ion gradients and the rise in the monosaccharide concentration is explained by the monosaccharide-induced restriction of the active ion transport and the resulting change in the energy dissipation in favor of monosaccharide transport. The $(Na^+ + K^+)$-ATPase in the brush border is discussed as the possible transmitter of energy from the ion gradients.

MOTILITY

3498 DYNAMIC RESPONSE CRITERIA FOR FLUID-FILLED ESOPHAGEAL MANOMETERS. (Eng.) Klingler, D. R.; Harell, G. S.; Zboralske, F. F. (Utah Biomedical Test Lab., 520 Wakara Way, Salt Lake City, UT 84108). *Invest. Radiol.* 12(6):515-519; 1977.

To ascertain the predominant frequencies in the peristaltic waveform, a system of two infused fluid-filled manometers was constructed in which each manometer responded in a significantly different manner to sinusoidal pressure fluctuations above 1 Hz in *in vitro* testing. Peristaltic pressure recordings *in vivo* in the distal third of the normal human esophageal body revealed no significant difference in the tracings obtained from the two manometers, indicating that only pressure fluctuations below 1 Hz were significant in determining the shape of normal distal esophageal peristaltic waveforms. Similar methodology may be applied for determining the predominant frequencies in other parts of the normal esophagus and for determining the predominant frequencies in esophageal motility disorders.

3499 ESOPHAGEAL MOTILITY IN THE ELDERLY. (Eng.) Khan, T. A.; Shragge, B. W.; Crispin, J. S.; Lind, J. F. (Univ. Manitoba Health Science Center, 700 William Ave., Winnipeg, Canada R3E 0Z3). *Am. J. Dig. Dis.* 22(12):1049-1054; 1977.

The effect of age on esophageal motility was studied manometrically by comparing 49 asymptomatic subjects over 60 yr of age with 43 similar subjects under 40 yr of age. The resting pressures and the responses to deglutition were recorded in the esophagus, lower esophageal sphincter (LES), and the stomach. Although the pressures in the LES were similar in the two groups, the LES response to deglutition was inadequate in 17.8% of swallows in those over 60 yr of age and in only 5.9% in those under 40 yr ($p<0.003$). Inadequate LES response was characterized by either a complete absence of response or absence of contractile phase. The amplitude of sphincteric response to deglutition was less in older persons, due mainly to a decrease in the amplitude of contraction. In the body of the esophagus the peristaltic contractions were weaker and progressed more slowly in the older group. The incidence of disordered contractions was significantly higher in the older group (25.3% versus 8.2%, $p<0.001$). Spontaneous gastroesophageal reflux was seen in 9 of the 49 subjects over 60 yr of age and in none under 40 yr of age. The changes in swallowing patterns indicate a degree of neuromuscular degeneration. They simulate those seen in neuromuscular esophageal disorders such as diffuse spasm and gastroesophageal reflux. Recognition of the age-related changes is important in interpreting esophageal motility patterns in the elderly.

3500 EFFECT OF ACID ON THE MOTILITY OF THE OESOPHAGUS OF THE PIG WITH EXPERIMENTALLY INDUCED OESOPHAGITIS. (Eng.) Punto, L.; Koivisto, E. (Dept. Diagnostic Radiology, Univ. Oulu, Oulu, Finland). *Scand. J. Gastroenterol.* 12(7):776-780; 1977.

Studies were performed to determine whether an acid contrast medium disturbs motor activity in the pig esophagus that has been damaged with hydrochloric acid. Eight pigs were used, two of them as control. Six animals were fed twice a day with 400 ml of HCl solution (pH 1.2) for 6 weeks. In five animals, a condition resembling esophagitis developed. Prior to the study and at intervals of 2 weeks, simultaneous radiologic and manometric examinations of the esophagus were performed, using the conventional barium sulfate or acid barium sulfate suspension as contrast media in 10-ml bolus doses. In two pigs, esophagoscopy was made three weeks after the test began. With conventional medium, all pigs showed normal peristalsis and pressure recordings of a normal swallowing complex with respect to amplitude, duration, and speed of peristaltic wave. Acid barium sulfate caused spasms and nonperistaltic pressure waves during swallowing of the contrast medium by four of the five pigs with experimental esophagitis, whereas, at the beginning of the experiment, normal peristalsis and swallowing complex had been present in all animals. In one animal, the changes were observed by 2 weeks after the beginning of experiment, while in the others they occurred after 6 weeks. The fact that control pigs did not show any pathological motor disturbances with acid contrast medium indicates that mucosal damage causes the motor disturbances provoked by the medium.

3501 PROSTAGLANDIN E_2 EFFECT ON LOWER ESOPHAGEAL SPHINCTER PRESSURE AND SERUM GASTRIN.

(Eng.) Maher, J. W.; Hollenbeck, J. I.; Crandall, V.; McGuigan, J.; Woodward, E. R. (Coll. Medicine, Univ. Florida, Gainesville, FL 32610). *J. Surg. Res.* 24(2):87-91; 1978.

The effects of 15-methyl analogs of prostaglandin E_2 (15 Me PGE_2) on lower esophageal sphincter pressure (LESP) and serum gastrin levels were studied in six mongrel dogs prepared with slit esophagostomies. After a 2-week recovery period, the dogs underwent three fasting esophageal motility studies, and blood was sampled for serum gastrin determinations. Esophageal motility studies and blood sampling were then repeated at 20, 30, and 40 min following i.v. injection of 15 Me PGE_2 (0.5 μg/kg). Serum gastrin was determined by radioimmunoassay, and LESP was measured as mean end expiratory pressure. Two additional dogs had motility studies repeated with 15 Me PGE_2 in doses 0.05, 0.2, 0.5, and 1.0 μg/kg to construct a complete dose-response curve in which the response was expressed as the change in LESP from basal values. All animals showed an increase in LESP after administration of PGE_2 when compared to the control value (from 29.2 ± 1.3 versus 19.2 ± 1.2 cm H_2O, $p<0.001$), the increase being large and significant ($p<0.005$) in four dogs and small and not significant in two dogs. The two dogs for whom dose-response curves were constructed also showed a large increase in LESP following injection of 15 Me PGE_2 (0.5 μg/kg). There were no differences in the response strength at the different time intervals measured. The LESP increased significantly following the administration of doses of 0.2, 0.5, and 1.0 μg/kg 15 Me PGE_2 while there was no significant increase at 0.05. Serum gastrin levels after administration of 15 Me PGE_2 (0.05 μg/kg) were unchanged from control studies (24.4 ± 5.0 pg/ml versus 16.2 ± 2.4 pg/ml). The studies strongly suggest that inhibition of gastrin release is not the mechanism of action of 15 Me PGE_2 on LESP. The usefulness of the drug as adjuvant therapy in peptic ulcer disease and reflux esophagitis awaits further study.

3502 EFFECT OF Salmonella typhimurium ON MYOELECTRICAL ACTIVITY IN THE RABBIT ILEUM.

(Eng.) Weisberg, P. B.; Carlson, G. M.; Cohen, S. (Sch. Medicine, Univ. Pennsylvania, Philadelphia, PA). *Gastroenterology* 74(1):47-51; 1978.

The small intestinal myoelectrical response to *Salmonella typhimurium* was studied using the ligated ileal loop model in male New Zealand white rabbits. Three strains of *S. typhimurium* were used: strain TML, which causes mucosal damage and increased fluid output; strain M-206, which causes increased fluid output but minimal mucosal damage; and strain LT-7, which causes mucosal damage but no increase in fluid output. Strains TML and M-206 produced groups of abnormal action potential bursts (APBs). An APB was defined as action potential activity by a duration of 1.5 sec or longer occurring in at least two adjacent electrode recording sites. The mean onset time of APB activity was 4.0 ± 0.5 hr after infection with TML and 5.25 ± 0.84 hr after infection with M-206 ($p>0.05$). After onset, the abnormal myoelectrical pattern persisted for the duration of all recording periods (up to 24 hr). Three distinct configurations of APBs were observed: (1) aborad propagation, (2) orad propagation, and (3) less organized bidirectional propagation from the point of origin, termed "splits." All APBs were associated with intestinal contractions. Strain LT-7 did not produce any APBs. Control experiments consisted of recording from noninfected loops, loops injected with sterile saline or sterile culture broth, loops infused with saline at 11.2 ml/hr, and loops infused with 800 mOsm of mannitol at 11.64 ml/hr. APB activity was not observed in any of the control experiments. These data indicate that, in addition to the secretory abnormalities seen in *Salmonella* diarrhea, there is a small intestinal myoelectrical disturbance consisting of abnormal APBs. The myoelectrical disturbance is seen with organisms known to produce increased fluid output, and it apparently occurs independently of the mucosal damage caused by *Salmonella*.

3503 EFFECTS OF ETHANOL ON ELECTRICAL PARAMETERS OF THE IN VIVO RAT STOMACH.

(Eng.) Biggerstaff, R. J.; Leitch, G. J. (Indiana Univ. Sch. Medicine, 8600 Univ. Blvd., Evansville, IN 47712). *Am. J. Dig. Dis.* 22(12):1064-1068; 1977.

The gastric transmural electrical potential difference (PD) and direct-current resistance were measured in the rat *in vivo* under conditions in which the luminal pH was controlled over the pH range 1.0 to 12.0. Raising the pH above 11.0 caused a reduction in both PD and resistance. This result is consistent with basic groups limiting cation permeability through the mucosa. Exposure of the mucosa to 20% ethanol caused a reduction in resistance, PD, and H^+ secretion, and an increased appearance of Na^+ in the lumen at neutral pH. The pH dependence of the resistance at high pH values was also eliminated, consistent with the elimination or bypassing of channels containing basic groups. Mucosal exposure to 8.5% ethanol reduced the PD and H^+ secretion without affecting resistance. Exposing the mucosa to a sucrose solution (1.2 M) that approximated the effective osmolarity of the 8.5% ethanol showed that the net Na^+ flux effect of this concentration of alcohol was probably due to its hyperosmolarity. Both the reduced PD and H^+ secretion seen with the alcohol solution, but not with the sucrose, indicated that the active transport inhibition by this concentration of alcohol was probably a direct effect of the ethanol.

3504 INHIBITORY EFFECT OF PENTAGASTRIN AND FEEDING ON NATURAL AND MOTILIN-INDUCED INTERDIGESTIVE CONTRACTIONS IN THE STOMACH OF CONSCIOUS DOGS. (Eng.) Itoh, Z.; Takeuchi, S.; Aizawa, I.; Couch, E. F. (Gunma Univ. Sch. Medicine, Maebashi, 371 Japan). *Gastroenterol. Jpn.* 12(4): 284-288; 1977.

The interaction between motilin, pentagastrin, and feeding was investigated during the interdigestive gastric motor state in four healthy conscious dogs. The i.v. infusion of synthetic motilin always induced a pattern identical with that of the naturally occurring interdigestive stomach contractions. Pentagastrin completely inhibited the interdigestive contractions at doses of 0.2-1.6 μg/kg/hr; this inhibition was dose-related to the occurrence of the motilin-induced contractions. Food ingestion strongly inhibited both the naturally occurring contractions and the motilin-induced contractions. These findings support the hypothesis that the interdigestive contractions in the dog are, at least in part, controlled by motilin.

3536 THE ROLE OF CALCIUM IN PAROTID AMYLASE SECRETION EVOKED BY EXCITATION OF CHOLINERGIC, α- AND β-ADRENERGIC RECEPTORS. (Eng.) Petersen, O. H.; Ueda, N.; Hall, R. A.; Gray, T. A. (Asahikawa Univ. Sch. Medicine, Asahikawa, Japan). *Pfluegers Arch.* 372(2):231-237; 1977.

Amylase output from superfused mouse parotid segments was monitored by an on-line automated fluorometric method. During exposure to Ca^{2+}-free solution containing 10^{-4} M EGTA (ethylene glycol-bis-[β-amino ethyl ether]), excitation of α-adrenoceptors or cholinergic receptors only resulted in a very small and transient increase (<10%) in amylase output. Admission of Ca^{2+} during sustained stimulation caused a marked, sustained rise in amylase output. During exposure to Ca^{2+}-free solution containing EGTA, excitation of β-adrenoceptors caused the usual marked rise in amylase output and the enhanced amylase secretion was sustained. Admission of Ca^{2+} during sustained isoproterenol stimulation only caused a small transient rise in amylase output. The effect of acetylcholine (ACh) on amylase output varied with the extracellular Ca^{2+} concentration, being reduced at subnormal extracellular levels and enhanced during superfusion with fluid containing 20 mM Ca^{2+}. Mn^{2+} (5 mM) acted as a stimulant of amylase secretion even in the presence of blocking agents for the cholinergic, α-, and β-adrenergic receptor sites. The effect of Mn^{2+} was biphasic; an initial transient increase in amylase output was followed by a slowly developing sustained increase in secretion. The initial response was abolished after pretreatment with EGTA in a Ca^{2+}-free solution. Adding 5 mM Mn^{2+} just after the addition of ACh had caused maximal amylase secretion resulted in an immediate reduction in amylase output. Adding Mn^{2+} and ACh simultaneously to the superfusion solution resulted in a response smaller than that expected for ACh alone. The effect of ACh during continued exposure to Mn^{2+} was greatly reduced compared to control conditions. Stimulation with Mn^{2+} during continued exposure to isoproterenol resulted in a marked transient increase in amylase output. The action of stimulants exciting cholinergic and α-adrenergic receptors is entirely dependent on extracellular Ca^{2+}, whereas the action of stimulants exciting adrenergic β-receptors is relatively independent of Ca^{2+}. Mn^{2+} immediately inhibits ACh-evoked amylase secretion probably by reducing Ca^{2+} influx. Mn^{2+} is, however, also a stimulant of amylase secretion, probably by displacement of membrane-bound cell Ca^{2+}.

SECRETION AND METABOLISM

Stomach

3545 STIMULI FOR INTESTINAL PHASE OF GASTRIC SECRETION IN DOGS.

(Eng.) Konturek, S. J.; Radecki, T.; Kwiecien, N. (Medical Acad., Krakow, Poland). *Am. J. Physiol.* 234(1):E64-E69; 1978.

In four dogs with a special gastroduodenal fistula that allowed complete separation of the stomach and the duodenum, various food chemicals (albumin, liver extract, amino acid mixture, individual amino acids, carbohydrate, fat, and saline) were instilled into the duodenum, and their ability to stimulate gastric acid and serum gastrin secretion were compared. The liver extract meal was the most effective stimulant of both gastric acid and serum gastrin secretion, whereas albumin and the amino acid mixture (made up to simulate the amino acid composition of albumin or liver extract) were less potent stimulants. The i.v. administration of the amino acid mixture was also an effective stimulant of gastric acid secretion but not of serum gastrin. Individual amino acids, instilled intraduodenally in 50 mM solutions, varied in stimulatory activity; the most active were serine, proline, glycine, leucine, and valine, whereas tyrosine, cysteine, aspartic acid, histidine, and tryptophan did not cause a significant increase of gastric acid secretion over saline control. L-isomers of the most active amino acids produced significantly greater acid outputs than did their D-isomers. The carbohydrate and fat meals in the intestine were ineffective in stimulation of gastric secretion. The results indicate that protein and its digestive products, peptides and amino acids, are stimulants of the intestinal phase of gastric secretion and that this stimulation involves release of gastrin, the direct action of the absorptive products on the oxyntic glands, and perhaps other mechanisms.

3546 MEASUREMENT OF GASTRIC ACID SECRETION IN ISOLATED GASTRIC MUCOSA OF THE RAT: EFFECTS OF SECRETAGOGUES AND INHIBITORS INCLUDING CYCLIC ADENOSINE MONOPHOSPHATE RELATED AGENTS AND AN H_2-RECEPTOR ANTAGONIST.

(Eng.) Watanabe, K.; Watanabe, H. Y.; Goto, Y.; Kariya, Y. (Dept. Pharmacometrics, Res. Inst. Wakan-yaku, Univ. Yoyama, Japan). *Chem. Pharm. Bull. (Tokyo)* 25(8):1934-1940; 1977.

An improved, reproducible, and sensitive method, which is a modification of the open stomach preparation of rats, for the measurement of gastric acid secretion in isolated rat gastric mucosa was used to measure the effects of certain secretagogues and antisecretory drugs in this system. This technique differs from the open stomach procedure by using immature rats that are not fasted before the experiment, by eliminating the stomach muscle layer, and by setting the pH-stat at 4.0. Dose-dependent acid secretory responses were obtained to all the tested secretagogues in the following dose ranges: 10^{-6}-10^{-4} g/ml histamine, 3×10^{-8}-3×10^{-6} g/ml bethanecol, 3×10^{-6}-6×10^{-5} g/ml tetragastrin, and 10^{-5}-10^{-3} g/ml dibutyryl cyclic AMP (DBcAMP); however, the maximum response to tetragastrin was always less as compared with that of other secretagogues. The effects of atropine (10^{-6} g/ml), metiamide (10^{-4} g/ml), Dibucaine (10^{-4} g/ml), sodium thiocyanate (10^{-3} g/ml), and 2,4-dinitrophenol (2,4-DNP, 10^{-4} g/ml) on acid secretion stimulated by bethanecol (10^{-6} g/ml), tetragastrin (10^{-5} g/ml), histamine (1×10^{-5} g/ml), and dibutyryl cyclic AMP DBcAMP (10^{-4} g/ml), were studied. Atropine achieved a significant inhibition ($p<0.01$) only against the action of bethanecol. Dibucaine and sodium thiocyanate strongly inhibited ($p<0.01$) the action of all the secretagogues. Metiamide significantly inhibited ($p<0.01$) the action of histamine and tetragastrin but only partially depressed ($p<0.05$) the action of bethanecol and was ineffective against DBcAMP. 2,4-DNP abolished the sensitivity of the gastric mucosa to all secretagogues ($p<0.01$) and even blocked basal secretion. Cyclic AMP (10^{-3} g/ml), cyclic guanosine monophosphate (cGMP, 10^{-4} g/ml), and DBcGMP (10^{-4} g/ml) failed to stimulate acid secretion, whereas theophylline (10^{-3} g/ml) gave a marked stimulation of acid output (change=1,200 ± 202 mμEq H^+/10 min) in tests to examine cyclic nucleotides other than DBcAMP. Imidazole (10^{-3} g/ml) significantly inhibited the action of bethanecol, histamine, and DBcAMP ($p<0.05$) and the action of tetragastrin ($p<0.01$). DBcGMP was ineffective as an antagonist of acid secretion and the results with prostaglandin E_1 (4×10^{-6} and 2×10^{-5}) were largely inconclusive except for inhibitory action against histamine ($p<0.05$).

3547 METABOLISM OF DOG GASTRIC MUCOSA: LEVELS OF GLYCOLYTIC, CITRIC ACID CYCLE AND OTHER INTERMEDIATES.

(Eng.) Sarau, H. M.; Foley, J. J.; Moonsammy, G.; Sachs, G. (Smith, Kline and French Lab., Philadelphia, PA 19101). *J. Biol. Chem.* 252(23):8572-8581; 1977.

Metabolites of glycolysis, the citric acid cycle, the hexose monophosphate shunt, glutamate, aspartate, and coenzyme A (CoA) were measured in defined parietal cell-enriched freeze-dried sections of dog gastric biopsies derived from nonsecreting and secreting tissue. In addition, NH_3, ribulose-5-phosphate, glycerol, and succinate were measured in perchloric acid extracts of biopsies. The onset of secretion increased the level of glycolytic intermediates including pyruvate and lactate with the most marked increase being in fructose-1,6-diphosphate levels (181%). The level of 6-phosphogluconate and ribulose-5-phosphate also increased (by 117% and 64%, resp.), in spite of a constant $NADP^+$/NADPH ratio. The levels of all the citric acid cycle intermediates measured also rose, the most marked increases being in malate and fumarate (by 136% and 183%, resp.). The levels of glycerol, acetyl-CoA, and CoA increased, but the ratio of the latter intermediates remained constant. Calculation of the ratio of the oxidized to reduced form of diphosphopyridine nucleotide indicated a fall of the ratio in the cytoplasm and a rise in the mitochondria. It is concluded that the major energy source for acid secretion is due to an increase in citric acid cycle activity and that glycolysis, and probably also fatty acid oxidation, is stimulated to provide mitochondrial substrate.

3548 EFFECT OF pH OF GASTRIC AND INTESTINAL MEALS ON GASTRIC ACID AND PLASMA GASTRIN AND SECRETIN RESPONSES IN THE DOG.

(Eng.) Konturek, S. J.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Physiol.* 233(6):E537-E543; 1977.

Studies were carried out in conscious dogs to determine the relationship between gastric acid secretion and changes in serum concentrations of gastrin and secretin in response to a meal at varying pH levels, when the meal was either confined to the stomach or perfused into the duodenum. In five dogs provided with a special cannula that allowed complete separation of the stomach and the duodenum, a 10% liver extract (LE) meal adjusted to pH levels ranging from 7 to 2 was introduced either into the stomach (gastric phase) or duodenum (intestinal phase). The LE meal (pH 7) in the stomach evoked an acid response equal to 75% of the maximal response to histamine; gastrin rose to about 230 pg/ml above the basal level. Acidification of the LE meal in the stomach resulted in a pH-dependent reduction in acid output and in gastrin levels; at pH 2, acid output was reduced by 85% and gastrin by 50%. Secretin was not changed by LE in the stomach at any pH. The LE meal (pH 7) in the duodenum stimulated gastric acid output to 30% of the histamine maximum and serum gastrin to about 40 pg/ml above the basal level. Acidification of the LE meal in the duodenum caused a pH-dependent fall in acid output, and, at pH 2, both acid output and gastrin level fell to the basal level. Conversely, secretin showed a pH-dependent increase, reaching 150 pg/ml above basal value at pH 2. Infusions of graded doses of secretin (0.25-2.0 U/kg/hr) during gastric or intestinal stimulation mimicked gastric acid and serum hormonal changes seen during duodenal acidification. In the intact stomach with undisturbed neural connections to the duodenum, a gastric LE meal was about three times as potent in stimulating gastric acid and serum gastrin release as an intestinal LE meal. Acidification of the LE meal produced inhibition of gastric acid output accompanied by a pH-dependent suppression of gastrin release in the gastric phase and a pH-dependent elevation of secretin release in the intestinal phase, but the decrease in gastrin and the increase in secretin do not fully account for the decreased acid secretion.

3549 EFFECT OF INDOMETHACIN AND ASPIRIN ON GASTRIC BLOOD FLOW AND ACID SECRETION.

(Eng.) Gerkens, J. F.; Shand, D. G.; Flexner, C.; Nies, A. S.; Oates, J. A.; Data, J. L. (Clinical Pharmacology, Vanderbilt Univ., Nashville, TN 37232). *J. Pharmacol. Exp. Ther.* 203(3):646-652; 1977.

The effect of indomethacin and aspirin on basal and pentagastrin-stimulated gastric blood flow and acid secretion was studied in two groups of pentobarbital-anesthetized dogs. In group I, blood flow was measured with an electromagnetic flow probe around the left gastric artery. Indomethacin (8 mg/kg, i.v.) and aspirin (100 mg/kg, i.v.) reduced basal blood flow by 45% and 26%, resp., but did not change the small basal acid output. Both drugs increased blood pressure. Infusions of pentagastrin (0.025-0.5 µg/kg/min) stimulated acid output and increased blood flow. Indomethacin, injected during the pentagastrin infusion, further increased acid output by a peak of 266%, and reduced blood flow by 43%. Aspirin increased acid output by 104% and reduced blood flow by 39%. In group II, blood flow to different parts of the stomach and small intestine was measured using radioactive microspheres. Pentagastrin infusion increased blood flow in the antrum (30%), fundus (76%), and cardia (45%), and indomethacin (1 hr after starting pentagastrin) reduced total gastric blood flow by 45% to below control levels, all regions being affected. The gastric mucosal and muscular layers were separated and 90% of total flow was to the mucosa. The increase in blood flow produced by pentagastrin and the decrease produced by indomethacin both occurred in the mucosa while muscular blood flow was not altered. Pentagastrin also increased blood flow in the duodenum, jejunum, and ileum, and indomethacin counteracted these increases but did not reduce flow below control. In group III, gastric arterial blood flow was increased by intra-arterial infusions of sodium arachidonate. Indomethacin and aspirin reduced these increases by 72% and 60%, resp. It is concluded that the reduction in mucosal blood flow and potentiation of stimulated acid output by indomethacin and aspirin may be a consequence of prostaglandin synthesis inhibition and that these actions may contribute to the ulcerogenic effect of these drugs.

3550 PROTECTIVE EFFECT OF CIMETIDINE ON ASPIRIN-INDUCED GASTRIC MUCOSAL DAMAGE.

(Eng.) MacKercher, P. A.; Ivey, K. J.; Baskin, W. N.; Krause, W. J. (Harry S Truman Memorial Veterans Hosp., Columbia, MO 65201). *Ann. Intern. Med.* 87(6):676-679; 1977.

The effect of cimetidine on aspirin-induced alterations in gastric mucosa was studied in five normal men. Aspirin effects were studied with and without previous treatment with cimetidine. The mean basal potential difference was -48 ± 1 mV. After 600 mg of aspirin p.o. in 1 dl of isotonic saline, the potential difference decreased in 10 min to -39 ± 1 mV ($p<0.001$) and returned to baseline within 60 min. Control biopsies showed 2% damaged mucosal cells compared with 20% damaged at the time of the maximal drop in potential difference ($p<0.001$) after aspirin. Recovery to 9% damage occurred by 60 min. In subjects pretreated p.o. with 300 mg cimetidine, the potential difference rose during 1 hr to -62 ± 1 mV ($p<0.001$). After aspirin potential difference fell to -48 ± 1 mV compared with -39 ± 1 mV with aspirin alone ($p<0.01$) and returned to -62 ± 1 mV at 60 min. The cimetidine-treated group showed 4% mucosal damage at the peak potential difference fall after aspirin, significantly less ($p<0.02$) than in the untreated subjects. The results indicate that cimetidine protects against aspirin-induced mucosal damage, mainly via decreased acid secretion.

3551 THE EFFECT OF INTESTINAL FAT ON HISTAMINE-STIMULATED GASTRIC SECRETION. (Eng.)

Wazna, M. F.; Stein, T.; Wise, L. (Long Island Jewish-Hillside Medical Center, New Hyde Park, New York, NY 11040). *J. Surg. Res.* 23(6):415-421; 1977.

The effect of intraduodenal fat infusion at a physiologic concentration (40 ml; 2 ml/min during first 10 min, 1 ml/min for the remaining 20 min) on histamine-stimulated gastric acid secretion was studied in female dogs with Heidenhain pouches. The dogs received histamine phosphate i.v. at a rate of 0.04 mg/kg/hr. There was a significant inhibition of acid output after fat administration (from 1.3 ± 0.1 to 0.5 ± 0.07 mEq/15 min, $p<0.001$), but there was no significant change in acid concentration. This result suggests that intraduodenal fat infusion inhibits gastric water secretion to the same extent as it inhibits gastric acid secretion. Histamine caused a marked initial increase in pepsin output ("washout" effect), followed by a secondary sustained increase. The intraduodenal administration of fat abolished the secondary increase in pepsin secretion. The depressant effect of intraduodenal fat on gastric acid and pepsin secretion may play a significant role in the prevention of peptic ulceration.

3552 CHARACTERIZATION OF ANTRAL GASTRIN CELLS WITH REGION-SPECIFIC ANTISERA. (Eng.)

Larsson, L. I.; Rehfeld, J. F. (Inst. Medical Biochemistry, Univ. Aarhus, Aarhus, Denmark). *J. Histochem. Cytochem.* 25(12):1317-1321; 1977.

Region-specific gastrin and cholecystokinin antisera are described. These antisera were used to characterize antral gastrin cells of mammalian (pig, dog, cat, rat) and submammalian (chicken, frog) species. A number of gastrin antisera, which in radioimmunoassay systems showed no or negligible cross-reactivity towards the structurally and functionally related peptide cholecystokinin, were found to react with both gastrin and cholecystokinin cells when used for immunocytochemistry. This discrepancy was shown to be due either to reactivity against a COOH-terminal region common to gastrin and cholecystokinin or to the occurrence of heterogenous antibody populations in the antisera. By differential absorptions, the latter type of antisera was rendered specific for gastrin. Antisera reactive against the NH_2-terminal, middle, or COOH-terminal regions of human heptadecapeptide gastrin were prepared and, together with a specific cholecystokinin antiserum, used for the characterization of antral gastrin cells of the different species. The results indicate that only the COOH-terminal region of gastrin is conserved during evolution.

3553 THE EFFECT OF GIH AND BOOTS SECRETIN AND CHOLECYSTOKININ ON DUODENAL ULCERS IN THE RAT. (Eng.)

Joffe, S. N.; Ferrie, M. M. (Royal Infirmary, Glasgow, G4 OSF, Scotland). *Acta Hepatogastroenterol. (Stuttg.)* 24(6):458-461; 1977.

The efficacy of preparations of secretin, cholecystokinin, and pancreozymin made by the Gastrointestinal Hormone Laboratory (GIH) or by Boots Pharmaceuticals in experimental duodenal ulcers was studied in 140 male Wistar rats. The rats were divided into six treatment groups: (I) 18 ml of saline (150 mmol) infused s.c. over 24 hr, (II) pentagastrin (4 µg/kg/min) and carbachol (0.8 µg/kg/min) in 18 ml of saline infused over 24 hr, (III) GIH secretin (0.125-1.00 clinical U/kg/hr) in 18 ml saline alone (a) or with pentagastrin and carbachol (b), (IV) Boots secretin (1-10 Crick-Harper-Raper [CHR] U/kg/hr) as in (a) or (b) above, (V) GIH cholecystokinin-pancreozymin (CCK-PZ, 1 Ivy-Dog U/kg/hr) as in (a) or (b) above, and (VI) Boots pancreozymin (1 CHR U/kg/hr) as in (a) or (b) above. After the experiment the animals were killed and the severity of lesions was graded on a scale from 0 to 6. Neither stomach nor duodenum mucosal changes were observed in groups I, III(a), IV(a), V(a), and VI(a). All rats from group II developed duodenal ulcers that had penetrated or perforated the serosa (grade 6). When GIH secretin was infused in a dose of 0.125 U/kg/hr with gastric secretagogues, the incidence of the ulcers was similar to that in rats given pentagastrin and carbachol alone. With increasing doses of GIH secretin, the incidence and severity of the secretagogue-induced lesions decreased, so that at 1 U/kg/hr, only 1/12 rats developed an ulcer. Boots secretin in doses 1-10 CHR U/kg/hr infused with the secretagogues had no protective effect. The Boots secretin was shown to be contaminated with CCK. Both GIH CCK-PZ and Boots pancreozymin, in combination with the secretagogues, produced a 100% incidence of duodenal ulcers, which were of greater severity and number than in the rats given the gastric secretagogues alone. In both clinical and laboratory studies, the hormone preparation used should be carefully considered to avoid the effect of contaminants.

3554 STUDIES ON GASTRIC MUCOSAL IgA: SEPARATION OF IMMUNOGLOBULIN RICH FRACTION FROM GASTRIC MUCOPROTEINS. (Eng.)

Spohn, M.; McColl, I. (Guy's Hosp. Medical Sch., London SE1 9RT, England). *Biochem. Biophys. Res. Commun.* 79(3):837-842; 1977.

Human gastric mucosal scrapings were subjected to fractionation on an isopycnic CsCl gradient to investigate the distribution of IgA of human gastric mucus and to compare it with the distribution of mucoproteins. IgA was found between the 5th and 10th ml from the top of the tube (total volume, 12 ml). After twofold fractionation, the combined IgA-containing fraction accounted for 4-7% of the total carbohydrate content of the original gastric mucosal scrapings. Gas-liquid chromatography of sugars showed the fraction to be enriched in mannose and *N*-acetyl glucosamine. The total carbohydrate content of the material was 5.5-7% by weight. Immunodiffusion against specific antisecretory component serum failed to demonstrate the presence of the secretory component in this fraction. It is concluded that gastric mucosal IgA, which appears to differ from a typical serum IgA in lacking the characteristic secretory component activity, can be separated from the carbohydrate-rich gastric mucoproteins by CsCl fractionation. This finding indicates the absence of covalent bonding between IgA and the mucoproteins of gastric mucus.

3555 PROSTAGLANDIN CYTOPROTECTION OF GASTRIC MUCOSA. (Eng.) Chaudhury, T. K.; Jacobson, E. D. (Univ. Texas Medical Sch., Houston, TX). *Gastroenterology* 74(1):58-63; 1978.

The possibility that prostaglandins protect the gastric mucosa by stimulation of the active transport of sodium was tested in dogs. Paired mucosal segments from the corpus of the stomach were mounted between bathing chambers to allow measurement of unidirectional fluxes of ^{22}Na, the electrical potential difference (PD) across the mucosa that is generated by the active transport of sodium, and the short-circuit current. The electrical resistance (R) was calculated from Ohm's law. The flux of ^{22}Na from serosa to mucosa ($J^{Na}_{s\to m}$)is an index of the passive transport of the ion and is a measure of membrane permeability. The difference between the two unidirectional fluxes (J^{Na}_{net}) represents the rate of active transport of the ion. If a topical damaging drug acted exclusively by increasing membrane permeability, one would anticipate the following responses to the agent: increased $J^{Na}_{s\to m}$, little effect on J^{Na}_{net}, decreased PD, and decreased R. Adding indomethacin (2.2×10^{-4} M) to the mucosal bathing solution caused no change in $J^{Na}_{s\to m}$, decreases in both J^{Na}_{net} and PD, and an increase in R. These findings suggest a primary effect on active transport of sodium. Effects of indomethacin on J^{Na}_{net}, PD, and R were reversed by 16,16 dimethyl prostaglandin E_2 (8×10^{-7} M) and by agents known to increase intracellular cyclic AMP content (theophylline and dibutyryl cyclic AMP). Incubation of mucosae with the prostaglandin increased measured cyclic AMP content 60% at a time before the full electrophysiological response. These data support the hypothesis that active transport of sodium is inhibited by a damaging agent and is stimulated by a protective agent, the latter appearing to act via increased accumulation of intracellular cyclic AMP.

3556 EFFECT OF 16,16-DIMETHYL PROSTAGLANDIN E_2 METHYL ESTER ON GASTRIC SECRETION INDUCED BY PENTAGASTRIN AND PEPTON [sic] MEAL IN MAN. (Eng.) Swierczek, J.; Kwiecien, N.; Oleksy, J.; Konturek, S. J. (Instytut Fizjologii, Grzegorzecka 16, 31-531 Krakow, Poland). *Acta Physiol. Pol.* 27(2):131-138; 1976.

The effect of 16,16-dimethyl prostaglandin E_2 methyl ester (PG/D, 1.25 μg/kg) on gastric secretion in 14 healthy male volunteers was studied to evaluate its usefulness in inhibiting gastric secretion and ulcer formation. Gastric secretion was stimulated by pentagastrin (i.v., 2 μg/kg/hr) or by a pepton meal (10% aqueous solution, continuous intragastric flow). The intragastric administration of PG/D resulted in 60% inhibition of gastric secretion in the first hour of the pentagastrin test; this inhibition diminished to 42% by the third hour; pepsin output was inhibited about 40% in the first hour. PG/D caused almost complete inhibition of gastric acid response to a pepton meal together with a marked decline of gastric pepsin concentration and serum gastrin concentration. PG/D caused a decline of total mucoprotein (TMP) output from 254 ± 52.59 to 164.4 ± 43.59 mg/hr from the first to the third hours, compared to a basal output of 82.4 ± 18.14 mg/hr and a control output of 80.9 ± 20.57 mg/hr, ($p<0.01$); the effect was due mainly to the fall in volume output since no significant changes in TMP concentration were found. No side-effects or changes in blood pressure, heart rate, body temperature, or results of laboratory tests were found during the secretory studies with PG/D or in succeeding 24 hr after PG/D administration. The possible usefulness of PG/D in the treatment of peptic ulcer disease is suggested.

3557 RENEWAL OF MOUSE GASTRIC MUCOUS CELLS FOLLOWING FAST NEUTRON IRRADIATION: AN ULTRASTRUCTURAL AND CARBOHYDRATE HISTOCHEMICAL STUDY. (Eng.) Wattel, W.; Geuze, J. J.; de Rooij, D. G.; Davids, J. A. G. (Medical Faculty, State Univ., Nicolaas Beetsstraat 22, Utrecht, Netherlands). *Cell Tissue Res.* 183(3):303-318; 1977.

Mouse gastric mucosa was studied ultrastructurally and histochemically after exposure to fast neutron irradiation, and the results were compared with those in the normal stomach. The number of cells per gastric gland was decreased after irradiation (1.0 MeV, 400 rads), and the glands were shorter. At day 9 following irradiation, several glands showed a dilated lumen lined by flattened cells. Between days 9 and 16, some of the glands disappeared. Parietal and chief cells disappeared from the remaining glands. At the same time, restoration of the mucosa started. At day 6, proliferative cells were scattered along the isthmus. As in controls, the isthmus contained a few undifferentiated cells, many differentiating surface mucous cells (SMC) with developing rough endoplasmic reticulum and silver proteinate-reactive Golgi element, and small secretory granules. At day 9, numerous proliferative cells were clustered in foci. Almost all these cells contained silver proteinate-reactive Golgi elements, granules, and vesicles. Most of them were SMC, others mucous neck cells (MNC) or intermediates. At day 16, proliferative foci were larger and consisted of differentiated mucous cells. Regenerated foveolae and glands consisted of large SMC and MNC and a few fibrillovesicular cells. In conclusion, proliferative activity is confined to undifferentiated cells and differentiating mucous cells, which identifies them as the progenitors of the other gastric cell types.

3558 STRESS ULCER--AN EXPERIMENTAL STUDY.

(Ger.) Kokoschka, R.; Gober, I.; Gebhart, W. (I. Chirurgische Universitatsklinik, Alser Strasse 4, A-1090 Vienna, Austria). *Wien. Klin. Wochenschr.* 89(16):553-562; 1977.

The effect of hypovolemic shock, induced by the withdrawal of blood from the femoral artery for 1-4 hr, on the perfusion of the stomach and the development of stress ulcer was studied in 14 mongrel dogs. Compared with an initial value of 66.73 ml/kg of body weight, the aortic blood flow was reduced to 46.79 ml/kg after 1-hr bleeding and to 36.37 ml/kg after 4 hr. The blood flow in the celiac artery was reduced from 6.56 ml/kg to 3.96 ml/kg after 4 hr, and the blood flow in the gastric artery, measured after bleeding for 4 hr, was 0.64 ml/kg versus an initial value of 1.62 ml/kg. The central venous pressure showed no significant change during the experiment, while the serum gastrin level dropped from 43.85 μg/ml to 33.66 μg/kg after 4 hr. Significant histological changes were seen in the gastric mucosa as a result of the hemodynamic changes, especially when the duration of the shock was 4 hr. All stages of stress ulcer from superficial erosion to deep ulcers were documented. Loss of the superficial epithelium and its replacement by necrobiotic zones and depletion and degranulation of mast cells were seen. The findings suggest that mast cells may play a mediator role in the pathogenesis of stress ulcer.

3559 CHANGES IN GASTRIC GLANDULAR CELL KINETICS AFTER SMALL BOWEL RESECTION IN THE RAT.

(Eng.) Seelig, L. L., Jr.; Winborn, W. B.; Weser, E. (Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX 75235). *Gastroenterology* 74(1):1-6, 1978.

The various types of gastric gland epithelial cells involved in the hyperplastic response to intestinal resection were studied in male Sprague-Dawley rats after a 50% resection involving the proximal small intestine. Two months after the operation, resected and control animals were given either a single or four successive i.p. injections of [^{3}H]thymidine (1 μCi/g). Animals from each group were killed 1 hr after the single injection and 3, 7, 30, and 60 days after the first multiple dose injection of [^{3}H]thymidine. At all periods after the multiple [^{3}H]thymidine doses, the percentages of labeled parietal and chief cells were significantly increased in animals with small bowel resection when compared with corresponding controls ($p<0.05$, $p<0.01$, $p<0.05$, and $p<0.001$ for parietal cells at each day, resp.; $p<0.01$, $p<0.05$, $p<0.001$, and $p<0.01$ for chief cells, resp.). The percentages of labeled mucous cells of the gastric glands were also increased in animals with small bowel resection at the 3- and 7-day periods. One hour after the single injection of [^{3}H]thymidine, the percentage of labeled gastric mucosal progenitor cells in animals with small bowel resection, although increased, was not significantly different from that in controls. It is, therefore, believed that the increases in percentage labeling of gastric glandular epithelial cells at 3, 7, 30, and 60 days could not solely be explained on the basis of an increased turnover rate of gastric progenitor cells. Rather, it might be concluded that the increase in glandular epithelial cells is accomplished, in part, by increased differentiation of gastric progenitor cells.

3560 FOLLOW-UP STUDY OF GASTRIN RESPONSE AFTER RESECTION OF THE JEJUNUM AND THE ILEUM.

(Eng.) Kajiwara, T.; Tamura, K.; Suzuki, T. (Kyoto Univ. Medical Sch., Shogoin, Sakyo-ku, Kyoto, 606, Japan). *Ann. Surg.* 186(6):694-699; 1977.

The effect of jejunal or ileal resection on gastrin release was studied in dogs. The i.v. infusion of L-arginine (0.5 g/kg for 30 min) was the most practical in evaluating gastrin release in addition to insulin and glucagon release. Serum gastrin levels in response to this dose of arginine were determined before, and 3 weeks, 3 months, and 1 yr after the resection of the jejunum or ileum. At 3 weeks, a significant increase in gastrin levels occurred in both the fasting state and after stimulation in dogs with either jejunum or ileum resection. At 3 months, the elevated gastrin response persisted only in those with jejunal resection. By 1 yr, the gastrin levels had fallen in almost all dogs to approximately the preoperative levels. These and other studies suggest that serum gastrin does not always play a main role in the hyperacidity in the later stage after massive intestinal resection.

3561 INCREASED MEAL-STIMULATED GASTRIC ACID SECRETION AND SERUM GASTRIN AFTER EXTENSIVE SMALL BOWEL RESECTION IN PUPPIES.

(Eng.) Wolf, S. A.; Telander, R. L.; Dozois, R. R.; Go, V. L. W. (Mayo Clinic, Rochester, MN 55901). *J. Pediatr. Surg.* 12(6):921-927; 1977.

The effects of massive resection of the small intestine (80% of the jejunum and ileum) on gastric acid secretion and serum gastrin level induced by feeding (ground boiled beef liver) were studied in six beagle puppies provided with vagally denervated pouches of the oxyntic gland area. Littermates were randomly assigned either as controls (nonresected) or as experimental (resected) animals. The mean basal acid output did not significantly differ within littermate pairs or between the entire control and resected groups (22 ± 8 and 20 ± 6 μEq/hr, resp.). However, the acid response during the 5th, 6th, 7th, and 8th hr after meal ingestion was significantly greater ($p<0.05$) in the resected group than in the control group. The cumulative acid output was 10.1 ± 1.8 mEq/8 hr in the resected group compared with 4.0 ± 1.4 mEq/8 hr in the control group ($p<0.05$). The mean fasting serum gastrin concentrations in control dogs (94 ± 10 pg/ml) did not significantly differ from those in resected dogs (64 ± 12 pg/ml). However, in littermate pairs, the mean serum gastrin concentrations at 6, 7, and 8 hr were significantly ($p<0.05$) greater in resected than in control puppies. Total integrated gastrin levels were significantly ($p<0.05$) less in littermate control puppies (22.3 ± 2.9 and 56.4 ± 15.7

ng/ml/8 hr) than in littermate resected puppies (61.3 ± 20.0 and 139.9 ± 19.6 ng/ml/8 hr). The integrated serum gastrin values during the 5th and 6th hr and during the 7th and 8th hr were significantly ($p<0.05$) greater after resection than before. The increase in gastric acid output correlated linearly with the acid and hypergastrinemia.

3562 EXPERIMENTAL GASTRIC SYMPATHECTOMY: AN EFFECTIVE PROPHYLAXIS OF GASTRIC STRESS LESIONS. (Eng.) Hottenrott, C.; Seufert, R. M.; Kuhne, F. W.; Busing, M. (Dept. Surgery, Univ. Heidelberg, Heidelberg, W. Germany). *Ann. Surg.* 186 (6):762-765; 1977.

The possible value of sympathectomy in the prevention of gastric stress ulceration was tested. Fifteen mini-pigs were bled to a mean aortic blood pressure of 40 mm Hg and maintained at that level for 3 hr. The control group consisted of eight animals with shock for 3 hr; the test group was comprised of seven animals with a similar shock period but they had undergone splanchnicectomy 14 days earlier. In all animals, a stimulated gastric secretion test was performed 3 days before and 8 days after splanchnicectomy. All controls showed severe gastric mucosal lesions after shock. Conversely, the piglets with splanchnicectomy developed no changes (5 animals) or only minor changes (2 animals). The efficacy of splanchnicectomy was confirmed by a stimulated gastric secretion test in which basal acid output did not change after operation (0.56 ± 0.35 mEq/1/30 min before and 0.20 ± 0.06 mEq/1/30 min after), but peak acid output increased significantly (from 2.99 ± 0.52 mEq/1/30 min to 5.35 ± 0.41 mEq/1/30 min, $p<0.0025$). This study suggests that gastric splanchnicectomy prevents gastric ulceration following experimental shock in pigs.

3563 ROLE OF THE SYMPATHETIC NERVOUS SYSTEM IN PEPTIC ULCER PRODUCTION IN RATS. (Eng.) Moraes, M. F.; Nyhus, L. M.; Kalahanis, N. G.; Bombeck, C. T.; Das Gupta, T. K. (Abraham Lincoln Sch. Medicine, P.O. Box 6998, Chicago, IL 60680). *Surgery* 83(2):194-199; 1978.

The role of the sympathetic nervous system in gastric acid secretion and in experimental cysteamine-induced (400 mg/kg, s.c.) duodenal ulceration was studied in male Sprague-Dawley rats. The animals were divided randomly into seven groups: (a) control, (b) sham-operated, (c) surgical sympathectomy, (d) chemical sympathectomy, (e) vagotomy, (f) surgical sympathectomy plus vagotomy, and (g) chemical sympathectomy plus vagotomy. Results on gastric acid secretion were expressed as gastric acid output (GAO=µEq of acid secretion in 1 hr). The means in the control and sham groups were 447.83 ± 26.67 GAO and 399 ± 36.4 GAO, resp. The means in the sympathectomized rats (surgically=562 ± 27.21 GAO and chemically=648.66 ± 46.53 GAO) were higher ($p<0.01$) than those of the control and sham groups. In the vagotomized group the mean was 156.6 ± 17.64 GAO, lower than those of the control and sham groups ($p<0.001$). The incidence of ulceration was 47.5% and 46% in the control and sham groups, resp. Both the sympathectomized groups (surgically, 73%; chemically, 77%), had a significantly elevated incidence of ulceration as compared with the controls ($p<0.01$). The vagotomized group had a 14% incidence of ulceration. These results indicate that sympathectomy affects both gastric acid secretion and the incidence of experimental peptic ulceration in rats.

3564 SURGICAL VAGOTOMY AND STOMACH WALL ATP AND ADP IN PYLORUS-LIGATED RATS. (Eng.) Mozsik, G.; Vizi, F. (Univ. Medical Sch., H-7643 Pecs, Hungary). *Am. J. Dig. Dis.* 22(12):1072-1075; 1977.

The stomach wall ATP and ADP levels were studied 24 hr after pylorus ligation in Wistar rats with and without bilateral surgical vagotomy. The amounts and concentrations of ATP and ADP significantly decreased in the corpus plus antrum and in the forestomach in pylorus-ligated rats ($p<0.001$), while the amounts and concentrations remained at a significantly higher level ($p<0.001$) in pylorus-ligated plus vagotomized rats. It is concluded that the breakdown of ATP is necessary to produce gastric hypersecretion and ulceration in pylorus-ligated rats. This decrease of cellular ATP can be prevented by bilateral surgical vagotomy.

3565 BODY WEIGHT AND GASTRIC ACID SECRETION IN RATS WITH SUBDIAPHRAGMATIC VAGOTOMY AND LATERAL HYPOTHALAMIC LESIONS. (Eng.) Opsahl, C. A.; Powley, T. L. (Yale Univ. Sch. Medicine, New Haven, CT 06508). *J. Comp. Physiol. Psychol.* 91(6): 1284-1296; 1977.

To investigate the role of the vagus in the lateral hypothalamic (LH) syndrome of body weight loss, male albino rats were divided into four groups: (a) animals with bilateral LH lesions that were subsequently given a bilateral subdiaphragmatic vagotomy, (b) LH animals that received a control vagotomy operation, (c) animals without lesions that underwent a subdiaphragmatic vagotomy, and (d) animals without lesions that underwent a control vagotomy operation. Both LH lesions and vagotomy reduced body weight levels, although the effects differed in terms of the length of time required to reach initial maximal loss, the time required to reach chronic levels of maintenance, and the severity of body weight reduction. Fasting gastric acid secretion was lowered by LH lesions ($p<0.05$), and the extent of this reduction was positively correlated with the reduction in body weight ($r=0.69$, $p<0.005$). Gastric contents after a 24-hr fast were greater in vagotomized rats than in nonvagotomized animals. The fact that the weight lowering effect of vagotomy was found to be much weaker in animals in which the lateral hypothalamus was intact than in the LH rats suggests that an intact lateral hypothalamus actively mitigates the effects of vagotomy. Alternatively, the exaggerated weight loss observed as a result of the combined LH-lesion-vagotomy procedure might be evidence that intact vagal innervation is actually involved in minimizing the effects on body weight of LH lesions.

3566 COMPARISON OF AMINO ACIDS BATHING THE PYLORIC GLAND AREA IN THE STIMULATION OF GASTRIC ACID SECRETION [Abstract]. (Eng.) Konturek, S. J.; Tasler, J.; Cieszkowski, M.; Wunsch, E. (Inst. Physiology, Medical Acad., Krakow, Poland). *Gastroenterology* 72(5, Part 2):1083; 1977.

SECRETION AND METABOLISM

Pancreas

3598 DEVELOPMENT OF THE EMBRYONIC MAMMALIAN PANCREAS: THE RELATIONSHIP BETWEEN MORPHOGENESIS AND CYTODIFFERENTIATION. (Eng.) Spooner, B. S.; Cohen, H. I.; Faubion, J. (Div. Biology, Kansas State Univ., Manhattan, KS 66506). *Dev. Biol.* 61(2):119-130; 1977.

The degree to which cytodifferentiation is obligatorily coupled to ongoing morphogenesis was analyzed in the developing mouse pancreas system. Protodifferentiated pancreatic epithelia were isolated from investing mesoderm and cultured on plastic substrata. Within 24 hr, the epithelia spread into two-dimensional monolayers. Under these conditions, acinar formation failed to take place. The cells did not undergo mitosis, a finding consistent with the absence of mesenchymal cells or mesenchymal factor from these cultures. In spite of the absence of morphogenesis, cytodifferentiation took place on schedule. Thus, over 5-7 days of culture, amylase specific activity rose 100-fold, and zymogen granules appeared in the cells. The results indicate that the regulation of exocrine cytodifferentiation is independent of ongoing morphogenesis.

3599 INTRACELLULAR DIVALENT CATION RELEASE IN PANCREATIC ACINAR CELLS DURING STIMULUS-SECRETION COUPLING. I. USE OF CHLOROTETRACYCLINE AS FLUORESCENT PROBE. (Eng.) Chandler, D. E.; Williams, J. A. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *J. Cell Biol.* 76(2): 371-385; 1978.

Stimulus-secretion coupling in pancreatic exocrine cells was studied using dissociated acini, prepared from mouse pancreas, and chlorotetracycline (CTC), a fluorescent probe that forms highly fluorescent complexes with Ca^{2+} and Mg^{2+} ions bound to membranes. Acini, preloaded by incubation with CTC (100 μM), displayed a fluorescence having spectral properties like that of CTC complexed to calcium (excitation and emission maxima at 398 and 527 nm, resp.). Stimulation with either bethanechol (100 μM) or cerulein (10 ng/ml) resulted in a rapid loss of fluorescence intensity and an increase in outflux of CTC from the acini. After 5 min of stimulation, acini fluorescence was reduced by 40% and appeared to be that of CTC complexed to Mg^{2+} (excitation and emission maxima at 393 and 521 nm, resp.). The fluorescence loss induced by bethanechol was blocked by atropine (5 μM) and was seen at all agonist concentrations that elicited amylase release. Maximal fluorescence loss, however, required a bethanechol concentration three times greater than that needed for maximal amylase release. In contrast, acini preloaded with 1-anilino-8-naphthalenesulfonate or oxytetracycline displayed no secretagogue-induced fluorescence changes. These results support the hypothesis that CTC is able to probe some set of intracellular membranes that release calcium during secretory stimulation and that this release results in dissociation of Ca^{2+}-complexed CTC.

3600 MORPHOLOGICAL CHANGES IN RAT PANCREATIC SLICES ASSOCIATED WITH INHIBITION OF ENZYME SECRETION BY HIGH CONCENTRATIONS OF SECRETAGOGUES. (Eng.) Savion, N.; Selinger, Z. (Hebrew Univ. Jerusalem, Jerusalem, Israel). *J. Cell Biol.* 76(2):467-482; 1978.

The morphological and biochemical characteristics of the inhibition of enzyme secretion seen with high concentrations of secretagogues were examined. Stimulation of enzyme secretion in rat pancreatic slices by cholinergic agonists or by cholecystokinin-pancreozymin (CCK-PZ) and its peptide analogs showed a biphasic dose response curve. The optimal concentrations eliciting an efficient rate of enzyme secretion were 1 μM for carbamylcholine or acetylcholine, and 5 nM and 20 nM for CCK-PZ octapeptide and CCK-PZ, resp. At higher concentrations of secretagogues, however, the rate of secretion progressively declined, and almost complete inhibition was achieved at 1 mM of carbamylcholine or acetylcholine and at 0.1 μM of CCK-PZ or its octapeptide analog. Atropine displaced the dose-response curve for carbamylcholine to the right so that in the presence of 7 μM atropine a concentration of 1 mM carbamylcholine gave an optimal rate of enzyme secretion. The ionophore A-23187 did not relieve the inhibition caused by supraoptimal concentrations of secretagogues, indicating that the inhibition occurs at the cellular rather than at the receptor level. Secretin had no effect on the inhibition of enzyme secretion by a high concentration of carbamylcholine, indicating that the inhibition was not caused by lack of water and electrolyte secretion. The energy-producing metabolism was not affected, since the ATP level in the pancreatic slices was the same in the presence of either inhibitory or optimal concentrations of secretagogues. The inhibition of enzyme secretion was reversible because restoration of efficient enzyme secretion occurred after removal of carbamylcholine (1 mM) by washing, followed by addition of an optimal concentration of CCK-PZ octapeptide. Morphological studies revealed that the presence of inhibitory concentrations of secretagogues caused severe distortion of the lumen structure: disruption of the filamentous system surrounding the lumen, disappearance of microvilli, and production of distended evaginations of the luminal membrane containing cellular material. These changes eventually caused a reduction in the size of the lumen, which became plugged with secretory material. These changes in the microtubular microfilamentous system could account for the inhibition of enzyme secretion.

3601 ON THE SECRETAGOGUE EFFECT OF DIBUTYRYL CYCLIC AMP IN THE RAT EXOCRINE PANCREAS. (Eng.) Bauduin, H.; Stock, C.; Launay, J. F.; Vincent, D.; Potvliege, P.; Grenier, J. F. (Free Univ. Brussels, Lab. Biochemical Pharmacology, B-1000 Brussels, Belgium). *Pfluegers Arch.* 372(1): 69-76; 1977.

Since the implication of cyclic AMP in the action of physiological stimuli is questionable and cyclic AMP and dibutyryl cyclic AMP (DbcAMP) are known to have dissociated effects in various tissues or cell types, the secretagogue property of the nucleotide derivative on the exocrine pancreas was investigated more thoroughly in rats. DbcAMP at a concentration of 0.1 mM or greater induced the discharge of exportable enzymes from rat pancreas fragments incubated *in vitro*. This effect was seen to be qualitatively similar to the action of physiological secretagogues acting via hormone receptors in the following ways. It was accompanied by the appearance of exocytotic images at the acinar cell apex. It was energy dependent, but the energy supply was low, while that required for the carbamylcholine or cerulein response was high and could only be afforded by oxidative phosphorylation. It was calcium dependent, but no alteration of inward or outward calcium movement was observed. Lastly, it was altered by agents (e.g., cytochalasin B) previously shown to disrupt the microfilamentous microtubular system. However, the secretory response to DbcAMP was quantitatively less than that obtained with hormonal stimuli. A damaging effect of DbcAMP on pancreatic acinar cells was ruled out on histological and biochemical grounds: there was no significant leakage of LDH, and protein synthesis, and 2-deoxy-D-glucose and L-leucine uptake were unaltered. The secretagogue effect of DbcAMP was reversible, dose-related, and specific. It was not mediated by neurotransmitter release or by interaction with their receptors. The evidence points to a direct interaction of DbcAMP with the pancreatic acinar cell and suggests the last step of the secretory cycle as the most probable site of action of the nucleotide derivative.

3602 PANCREATIC EXOCRINE SECRETION IN ANESTHETIZED AND CONSCIOUS RATS. (Eng.) Petersen, H.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Am. J. Physiol.* 233(6):E530-E536; 1977.

Pancreatic secretion in response to graded doses of secretin and cholecystokinin was studied in conscious and anesthetized Sprague-Dawley rats. During the first 2 to 5 days after the pancreatic fistula was prepared, basal pancreatic volume and protein outputs increased markedly in the conscious rats, reaching levels more than 10 times greater than in anesthetized rats. Maximal bicarbonate output in response to secretin was more than four times greater in conscious than in anesthetized rats, but the maximal protein response to cholecystokinin was similar in the two states. In conscious rats, recirculation of bile plus pancreatic juice into the duodenum caused a significant decrease in bicarbonate and protein outputs (43% and 59% lower, resp.). Without recirculation, basal protein output was as high as the maximal response to cholecystokinin with recirculation and was not increased by exogenous cholecystokinin. The findings support the hypothesis that, unlike anesthetized rats, conscious rats have a high basal rate of spontaneous release of cholecystokinin and that this can be partially suppressed by recirculation of bile plus pancreatic juice. The responses of rats to secretin and cholecystokinin are greatly affected by the time that has elapsed since surgical preparation and by whether bile and pancreatic juice are recirculated into the gut.

3603 EFFECTS OF CHRONIC ALCOHOL ADMINISTRATION ON THE EXOCRINE PANCREATIC SECRETION OF THE CONSCIOUS RAT: A FOLLOW-UP STUDY. (Fre.) Laugier, R.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM U-31, 46, chemin de la Gaye, F 13009 Marseille, France). *Gastroenterol. Clin. Biol.* 1(10):767-774; 1977.

The effect of long-term alcohol consumption on basal exocrine pancreatic secretion and on secretion stimulated by the intraduodenal instillation of oleic acid was studied in adult male Sprague-Dawley rats. The animals received water *ad libitum* in which the alcohol content was increased from 5 to 20% over a 3-week period and maintained at 20% during the rest of the experiment (4, 8, or 12 months total length). Control rats received normal drinking water. Water and bicarbonate secretions were decreased at the 4th month of chronic alcohol consumption, but then returned to normal. However, protein secretion (both concentration and output) was increased at the beginning of the 4th month. In the 8th month, the basal protein output in the treated rats was more than twice as high as in the controls, and it could no longer be stimulated by intraduodenally administered oleic acid. The protein secretion seemed to have spontaneously reached its maximum. During the 12th month, the basal protein secretion in the treated rats was significantly lower than in the controls, and it was still not stimulated by oleic acid. This phenomenon could be explained by the progression of chronic pancreatic lesions that reduce the maximum secretory capacity of a hyperfunctioning pancreas. The findings indicate that chronic alcoholism at first reduces the basal and stimulated bicarbonate secretion, which phenomenon is then followed by changes in enzyme secretion. The increased protein secretion is the steadiest sign, before the onset of pancreatic insufficiency, of the effect of chronic alcoholism on the pancreas.

3604 THE EFFECT OF CHRONIC ETHANOL INGESTION ON THE PANCREATIC PROTEOLYTIC ENZYMES AND THEIR INHIBITORS IN THE RAT. (Eng.) Jalovaara, P.; Huttunen, R. (Dept. Anatomy, Univ. Oulu, 90220 Oulu 22, Finland). *Scand. J. Gastroenterol.* 12(7): 786-792; 1977.

The effect of chronic ethanol ingestion on pancreatic proteinases and their inhibitors, as well as some routinely assessed indices of pancreatic activity, were studied in 19 young inbred Long Evans male rats and 16 control animals. Ethanol (20% weight/volume, 1.1 ml/100 g of body weight) was administered by gastric intubation 5 times/week for 10-12 weeks. The general condition of animals, body weight gain, and the serum levels of hepatic transaminases did not change; the serum cholesterol level and the amount of trypsinogen, chymotrypsinogen, and specific and total casein hydrolizing activities in pancreatic homogenates did not differ significantly between the experimental and control groups. The activities of plasma enzymes commonly used as indicators of hepatic cell injury showed no difference between the control and experimental groups. Levels of blood amylase and serum triglycerides, the amount of soluble proteins in the homogenates, the specific and total BAPNA (*N*-alphabenzoyl-DL-arginine-4-nitroanilide-hydrochloride) hydrolyzing activities, and the total ATEE (*N*-acetyl-L-tyrosine ethyl ether) hydrolyzing activity were lower in the rats subjected to alcohol administration than in controls ($p<0.05$, $p<0.001$, $p<0.001$, $p\leq0.01$, $p\leq0.001$, and $p\leq0.01$, resp.). The trypsin inhibition of the homogenates was more pronounced and the plasma protein content was higher ($p<0.05$) in ethanol-treated rats, but the trypsin-inhibiting and trypsin-protecting capacities of the plasma were lower in the experimental group than in controls ($p\leq0.01$ and $p\leq0.001$). The results suggest that chronic ethanol ingestion in rats impairs protein synthesis in the pancreas leading to atrophy that corresponds to the clinical picture of chronic pancreatitis. Simultaneously, the protection mechanism of the blood against proteolytic enzymes is also impaired.

3605 INFLUENCE OF GLUCAGON ON EXOCRINE PANCREATIC FUNCTION AS DETERMINED BY THE LUNDH TEST IN DOGS. (Eng.) Gyr, K.; Kayasseh, L.; Stalder, G. A.; Rittmann, W. W.; Girard, J. (Kantonsspital, CH-4004 Basel, Switzerland). *Am. J. Vet. Res.* 38(12):1949-1952; 1977.

To standardize the Lundh test in dogs and to assess the extent to which the results are modified by glucagon administration, exocrine pancreatic function was investigated by the Lundh test in dogs with chronic duodenal and gastric fistulas. The mean tryptic activity detected in 18 tests in six dogs was 32.25 ± 5.25 μEqH+/min/ml, which is considerably higher than that observed in man. The administration of glucagon (5 or 10 μg/kg, i.v.) was followed at 30-60 min by a significant decrease (30.8%, $p<0.05$) in the volume of the duodenal contents and a more pronounced depression of the enzyme concentrations (trypsin 59%, chymotrypsin 53.3%, $p<0.02$). It is concluded that the Lundh test affords a valuable experimental model for the investigation of exocrine pancreatic function in dogs.

3606 METHADONE BLOCKADE OF 2-DEOXYGLUCOSE-INDUCED PANCREATIC SECRETION IN THE RAT: EVIDENCE FOR A CENTRAL SITE OF ACTION. (Eng.) Roze, C.; Chariot, J.; de La Tour, J.; Souchard, M.; Vaille, C.; Debray, C. (Hopital Bichat, 170 Blvd. Ney, 75877 Paris Cedex 18, France). *Gastroenterology* 74(2, Part 1):215-220; 1978.

The effects of methadone on pancreatic exocrine secretions were tested in male Wistar rats under basal conditions and following hormonal stimulation by secretin (0.125 U/kg/min) and cerulein (110 and 330 ng/kg) or after stimulation by the differentially acting cholinergic agents acetylcholine, 2-deoxyglucose, and electrical stimulation of the vagus. Methadone (2.5 or 5 mg/kg, s.c.) had no effect on basal hydroelectrolytic secretion. It decreased basal enzyme secretion very slightly. The stimulatory effects of 2-deoxyglucose (75 mg/kg, i.v.) were completely blocked by methadone at 5 mg/kg, and this blockade was reversed by nalorphine at 6 to 9 mg/kg. At 100 μg, methadone blocked 2-deoxyglucose effects when injected into brain ventricles, but the same dose was ineffective when systemically introduced. The effects of secretin, cerulein, acetylcholine, and electrical stimulation of the vagus were not depressed by methadone. These results strongly suggest that the methadone blockade of 2-deoxyglucose effects occurs at a central level and is mediated by narcotic drug receptors.

3607 EFFECT OF A SYNTHETIC ANALOGUE OF PGE_2 ON EXOCRINE AND ENDOCRINE PANCREATIC FUNCTION IN THE RAT. (Eng.) Dodi, G.; Santoro, M. G.; Jaffe, B. M. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Surgery* 83(2):206-213; 1978.

The effect of 16,16-dimethyl prostaglandin E_2-methylester (di-M-PGE_2) on exocrine and endocrine pancreatic secretion was studied in male Lewis rats with chronic pancreatic fistulas. Under basal conditions as well as after stimulation with secretin and cholecystokinin octapeptide (OP-CCK), pancreatic exocrine secretion was markedly inhibited by the i.v. injection of di-M-PGE_2 at 10 μg/kg and 100 μg/kg. Secretory volumes and bicarbonate and protein outputs decreased within 10 min after the administration of di-M-PGE_2, and this inhibitory effect persisted throughout the following 40 min. The smaller dose of di-M-PGE_2 (10 μg/kg, PG-10) inhibited the volume of pancreatic secretion by an average of 47.7% and decreased bicarbonate and protein output by 41.1% and 70.5%, resp. The larger dose (100 μg/kg, PG-100) caused a mean 48.3% inhibition of pancreatic secretory volume and decreased bicarbonate and protein outputs by 41.7% and 64.5%, resp. Plasma insulin levels were lowered markedly after injection of di-M-PGE_2 under basal conditions (mean inhibition 63.1% by PG-10 and 55.3% by PG-100) as well as after secretin stimulation (mean inhibition 89.5% by PG-10 and 82.4% by PG-100). These observations document that di-M-PGE_2 is a potent inhibitor of pancreatic exocrine and endocrine function in unanesthetized rats. The PGE_2-analogue antagonized the stimulatory effects of both secretin and OP-CCK.

3608 EFFECT OF PANCREATIC DUCT LIGATION ON EXOCRINE PANCREATIC FUNCTION AND STRUCTURE IN THE RABBIT. (Eng.) Arvanitakis, C.; Folscroft, J. (Kansas Univ. Sch. Medicine, Kansas City, KS 66103). *Experientia* 15(1):77-79; 1978.

The effect of pancreatic duct ligation, which is used as an experimental model of pancreatic insufficiency, on exocrine pancreatic function and structure was studied in the rabbit. Four weeks after pancreatic duct ligation, fecal and luminal chymotrypsin were detected in concentrations similar to those in sham-operated controls. Pancreatic changes in the ligated group included marked dilatation of the main pancreatic duct, proliferation and distention of ductules, and fibrosis. Despite pancreatic duct ligation and fibrosis, proteolytic enzymes continued to secrete into the duodenal lumen. These results suggest that pancreatic duct ligation in the rabbit is not associated with total pancreatic insufficiency.

SECRETION AND METABOLISM

Hepatobiliary Tract

3630 RAT HEPATOCYTE PRIMARY CELL CULTURES. III. IMPROVED DISSOCIATION AND ATTACHMENT TECHNIQUES AND THE ENHANCEMENT OF SURVIVAL BY CULTURE MEDIUM. (Eng.) Williams, G. M.; Bermudez, E.; Scaramuzzino, D. (American Health Foundation, 1 Dana Rd., Valhalla, NY 10595). *In Vitro* 13(12): 809-817; 1977.

Techniques for dissociation and attachment of rat hepatocytes as well as modifications of the culture medium that enhance *in vitro* survival of the cells are described. The 4-min washout perfusion of livers from adult male Fisher rats was performed with 0.5 mM ethylene glycol-bis-(β-amino ethyl) *N*,*N*'-tetracetic acid in Ca^{++}-Mg^{++}-free Hank's balanced salt solution buffered with 0.05 M *N*-2-hydroxy-ethyl-piperazine-*N*'-2-ethanesulfonic acid (HEPES) to pH 7.2. The 10- to 12-min enzyme perfusion was performed with collagenase solution (100 U/ml) in Williams' medium E (WE) buffered to pH 7.4 with 0.05 M HEPES, and during it, the flow rate was decreased gradually from 40 to 20 ml/min. Following perfusion, cells were detached by combing into fresh collagenase solution, centrifuged at 50 x *g* for 4 min, resuspended with a 25 ml wide-mouthed pipette, and inoculated into 25 cm^2 plastic flasks in 5.0 ml of WE with 10% fetal bovine serum and 50 μg/ml gentamicin. The attachment interval lasted 1.5 hr to permit attachment only of viable cells. The effect of four culture media (Eagle's Minimum Essential Medium, Leibovitz's L-15, Ham's F-12, and a newly formulated medium containing galactose) on attachment and survival of cells was studied. Reduction of the perfusion rate decreases the amount of collagenase solution required. Gradual reduction of the flow rate of the enzyme perfusion did not alter the viability or yield, but preserved the histology of the liver and decreased the amount of collagenase solution required. Dissociation in enzyme solution increased the viability of the final suspension to 69 ± 16% in comparison with 38 ± 17% after dissociation in WE. Postdissociation enzyme exposure (15 min in collagenase and hyaluronidase) reduced the recovery of viable cells from 100 to 64 ± 31% and the attachment efficiency from 30 ± 11 to 11 ± 11% ($p<0.01$) and thus is not recommended. When all the tested procedures were combined into the described modified method, the average percentage of free nuclei decreased (40-10%), the viable cells recovered ($92 \pm 53 \times 10^6$ to $164 \pm 70 \times 10^6$ cells/100 g body weight), the percentage of viable cells increased (43 ± 15 to 79 ± 7%), and the percentage of attachment efficiency increased (25 ± 9 to 42 ± 11%). The volume of medium present during attachment was a critical factor: the 5-ml volume gave a 50% attachment efficiency compared to a 20% attachment efficiency in a 2-ml volume. Additional investigations indicated that the effect was due to enhanced viability of unattached cells in the larger volume environment and not due to dilution of any residual collagenase. Eagle's medium, WE, L-15, and F-12 supported culture survival to similar extents, although average survival in L-15 appeared slightly better than in the others; the newly-formulated, galactose-containing medium was comparable to L-15 in this respect. The improved conditions described enhance the final recovery of viable liver cells and the attachment efficiency of liver cells *in vitro*.

3631 EVALUATION OF HEPATOCELLULAR AND KUPFFER CELL FUNCTION OF THE ISOLATED GUINEA PIG LIVER PERFUSED BY A FLUOROCARBON MEDIUM.

(Eng.) Roeser, H. P.; Cooksley, W. G. E.; Mack, S. (Royal Brisbane Hosp., Herston, Brisbane, 4029, Queensland, Australia). *Gastroenterology* 74(2, Part 1):209-214; 1978.

A synthetic medium for isolated guinea pig liver perfusion, using a fluorocarbon (FC) emulsion as the oxygen-carrying agent, was evaluated for its capacity to maintain liver viability and function. A 10% emulsion of perfluorotributylamine (FC43) was dispersed by a nonionic detergent (Pluronic F68) in a buffered electrolyte solution. The FC43 perfusate was compared with identical media in which FC43 was either omitted or replaced by 20% isologous RBC. Damage to liver cells was assessed by hepatic flow rate, aspartate aminotransferase release, and liver histology. Bile secretion, albumin synthesis, and galactose elimination capacity were used as indices of parenchymal cell function, and Kupffer cell activity was assessed by uptake of colloidal radioactive gold. All three perfusion media satisfactorily maintained liver cell viability, but the two media supplemented with a specific oxygen-carrying agent were associated with significantly superior parenchymal cell function ($p=0.05-0.01$). The performance of the FC and RBC media was not significantly different. The phagocytic activity of Kupffer cells was well sustained by all three media, but the FC medium was superior with large amounts of colloidal gold. Iron release from hepatic parenchymal cells, with the FC medium, was similar to that reported for rat liver preparations, using a RBC perfusate.

3632 HEPATIC CLEARANCE OF DRUGS. III. ADDITIONAL EXPERIMENTAL EVIDENCE SUPPORTING THE "WELL-STIRRED" MODEL, USING METABOLITE (MEGX) GENERATED FROM LIDOCAINE UNDER VARYING HEPATIC BLOOD FLOW RATES AND LINEAR CONDITIONS IN THE PERFUSED RAT LIVER IN SITU PREPARATION.

(Eng.) Pang, K. S.; Rowland, M. (Natl. Inst. Health, Bethesda, MD 20014). *J. Pharmacokinet. Biopharm.* 5(6):681-699; 1977.

The disposition of the lidocaine metabolite, monoethylglycine xylidide (MEGX), was studied in a perfused rat liver *in situ* preparation in an attempt to discriminate further between two models of hepatic drug clearance. In the "well-stirred" model, the liver is regarded as a well-stirred compartment with the emergent drug concentration in equilibrium with that in the liver. In the "parallel tube" model, the liver is viewed as a series of identical parallel units with enzymes distributed evenly around the units. Using a single passage perfusate system, it was found in a previous study that the extraction ratio of lidocaine was maximal and constant (0.997) below 7 mg/l. The steady-state output MEGX concentration appearing in the emergent blood upon a constant and low input concentration of lidocaine (4 mg/l) was determined under varying hepatic blood flow rates (10-16 ml/min/liver). The data suggest that, operationally, the well-stirred model adequately describes the appearance of MEGX from lidocaine.

3633 MASSIVE LIVER ENLARGEMENT ACCOMPANIED BY DECREASED DRUG METABOLISM. EFFECT OF ANTERIOR PITUITARY EXTRACT ON HEPATIC ULTRASTRUCTURE, ZOXAZOLAMINE PARALYSIS, AND METABOLISM IN THE RAT.

(Eng.) Szabo, S.; Garg, B. D.; Kourounakis, P.; Tuchweber, B. (Harvard Medical Sch., Boston MA 02115). *Can. J. Physiol. Pharmacol.* 55(5):1135-1142; 1977.

The relationship between liver enlargement and drug metabolism was investigated in female Sprague-Dawley rats. Hepatomegaly (e.g., 31% increase in liver weight in a 17-day experiment) was induced by injection of lyophylized anterior pituitary (LAP) extract (20 mg, s.c. twice daily for 4-34 days). The liver enlargement seemed to be due to an increase in the number and the size (enhanced water content and PAS-positive material) of hepatocytes. Electron microscopy of the liver revealed slight proliferation of the smooth endoplasmic reticulum and pronounced fragmentation and dilation of the rough endoplasmic reticulum. Zoxazolamine paralysis time was significantly prolonged (+55% and +102%) after 4 and 17 days, resp., of treatment with LAP. Metabolism of zoxazolamine by the 9,000 x *g* supernatant fraction of the liver of rats given LAP for 17 days was reduced by 73%. Thus, the marked hepatomegaly induced by LAP was associated with a prolonged action of the drug, which may result from a decrease in hepatic drug metabolism.

3634 CHOLERESIS AND HEPATIC TRANSPORT MECHANISMS. III. BINDING OF OUABAIN AND K-STROPHANTHOSIDE TO BILIARY MICELLES AND INFLUENCE OF CHOLERESIS ON THEIR BILIARY EXCRETION.

(Eng.) Vonk, R. J.; Van Doorn, A. B. D.; Scaf, A. H. J.; Meijer, D. K. F. (Dept. Pharmacology, State Univ. Groningen, Bloemsingel 1, Groningen, Netherlands). *Naunyn Schmiedebergs Arch. Pharmacol.* 300(2):173-177; 1977.

To investigate binding of drugs to biliary micelles as a possible factor in the hepatic transport process, the interaction of two uncharged compounds, ^{3}H-ouabain and ^{3}H-K-strophanthoside with biliary micelles was studied by ultracentrifugation of rat bile. The bile acids normally present in rat bile were predominantly associated with cholesterol-containing micelles, but not to the same extent. The tendency of the bile salts to be associated with mixed micelles was the greatest for conjugated chenodeoxycholate, lower for conjugated deoxycholate, and the least for conjugated cholate. The sedimentation patterns of the water soluble cardiac glycosides, added *in vitro*, indicated binding to mixed biliary micelles as well as noncholesterol-containing micelles. Mannitol was found to be associated with both categories of biliary micelles. In spite of the binding of cardiac glycosides to the micelles, the administration of taurocholate did not stimulate biliary output of the glycosides. The administration of the choleretics dehydrocholate and ethacrynic acid failed to enhance biliary output of the glycosides. These results indicate that binding of drugs to biliary micelles diminishes the free concentration of drugs in bile and confirm earlier studies with organic anions that binding to biliary micelles is not a pertinent factor in the rate of biliary excretion.

3635 BILE-SALT-DEPENDENT AND INDEPENDENT CHOLERESIS INDUCED BY BUCOLOME IN THE RAT.

(Eng.) Kitani, K.; Morita, Y.; Miura, R.; Kanai, S. (Tokyo Metropolitan Inst. Gerontology, 35-2, Sakaecho, Itabashi-ku, Tokyo 173, Japan). *Can. J. Physiol. Pharmacol.* 55(5):1155-1161; 1977.

The bile salt pool was studied in male Wistar rats in which choleresis was induced by 1-cyclohexyl-5-*n*-butyl-2,4,6-trioxoperhydropyrimidine (bucolome, BC). The rats received BC (20 mg/100 g) i.p. [^{14}C]erythritol and mannitol clearance studies indicated that this choleresis was of canalicular origin. In 1-hr continuous bile collection studies, immediately after the interruption of enterohepatic circulation (acute interruption), the bile flow rate was considerably increased and the bile salt excretion rate was significantly increased ($p<0.05$) in rats that received BC. However, the bile salt excretion rate fell rapidly in BC-administered rats, while the bile flow rate was fairly constant during this 1-hr period. Thus, unlike the situation in control rats, bile flow rate was not significantly correlated with the bile salt excretion rate in BC-administered rats. In rats that had an external bile fistula open for 16-20 hr (chronic interruption of enterohepatic circulation), the bile flow rate was also significantly increased ($p<0.01$) by BC administration, while the bile salt excretion rate was not changed after BC administration. It is suggested that BC induced bile salt-independent choleresis in both experimental rat groups (acute and chronic interruption of enterohepatic circulation). In addition, BC appeared to increase the bile salt-dependent fraction of bile in rats with acute interruption of enterohepatic circulation, possibly by mobilizing the bile salt pooled in the intestinal content and/or intestinal wall.

3636 CHARACTERIZATION OF METHYLUMBILLIFERONE (MENDIAXON®)-INDUCED CHOLERESIS IN THE ISOLATED PERFUSED RAT LIVER.

(Eng.) Kroker, R.; Anwer, M. S.; Hegner, D. (Fachbereich Tiermedizin, Univ. Munchen, Veterinarstr. 13, D-8000 Munchen 22, W. Germany). *Acta Hepatogastroenterol.* 24(5):348-354; 1977.

Studies were performed on isolated perfused livers from male Wistar rats to characterize the influence of the choleretic drug, methylumbilliferone, on bile formation. In experiments on the time-dependent influence of methylumbilliferone (10 mg/liver), the drug increased bile acid secretion (from 34 to 61 nmol/g liver), bile flow (from 14.8 to 28 µl/g liver), and sodium excretion (from 2.5 to 5.0 µmol/g liver), all within 20 min of the addition of the drug. Bile acid secretion decreased to 3.5 nmol/g liver by 100 min after addition of the drug (60 min of perfusion), compared to a value of 14 nmol/g in controls at this time. Methylumbilliferone was shown not to affect the assay used for bile acid estimation. The dose-dependent effect of methylumbilliferone on bile flow and bile acid secretion was examined. The maximal effect was observed at a final concentration of 1.13 mM, resulting in a 110% increase of bile flow and a 150% increase in bile acid secretion; concentrations below 5.6 mM did not alter either parameter. The erythritol clearance rate was measured before and after the administration of methylumbilliferone and plotted against bile flow, yielding a slope of essentially 1 in both cases. This result indicates that all the bile is of canalicular origin. Calculation of the relative increases of sodium excretion and bile flow yielded a significantly correlated ($r=0.99$) regression line, which indicates that the increased bile flow was due in part to the elevated sodium excretion. Analysis of the bile for the hydrolyzed drug demonstrated that the increased bile flow was also due in part to the excreted portion of methylumbilliferone. These results indicate the complexity of hepatic organic anion excretion.

3637 THREE METHODS FOR MEASURING THE INCREASE IN THE CAPACITY OF THE DISTENDED BILIARY TREE IN THE RAT PRODUCED BY α-NAPHTHYLISOTHIOCYANATE TREATMENT.

(Eng.) Olson, J. R.; Fujimoto, J. M.; Peterson, R. E. (Medical Coll. Wisconsin, Wilwaukee, WI 53233). *Toxicol. Appl. Pharmacol.* 42(1):33-43; 1977.

As one step in attempting to understand structure-function relationships, studies aimed at measuring one structural feature were undertaken. The capacity of the distended biliary tree was measured in male Sprague-Dawley rats by three techniques: retrograde intrabiliary injection (RII), segmented retrograde intrabiliary injection (SRII), and retrograde pushback (RPB). Biliary tree distention was produced by the administration of α-naphthylisothiocyanate (ANIT, 45 mg/kg/day) in olive oil by gavage for 8 days. Control rats, which received 0.2 ml of olive oil daily for 8 days, had distended capacities of 33.4 ± 2.7, 34.1 ± 3.4, and 31.6 ± 2.9 µl by the RII, SRII, and RPB techniques, resp., at 15 days after the treatment. In treated rats, the RII, SRII, and RPB techniques gave distended biliary capacities of 48.0 ± 1.6, 47.5 ± 1.4, and 46.8 ± 1.3 µl, resp. In controls, the two-way analysis of variance showed no significant difference between the three methods. For each of the three methods, the mean distended biliary tree capacity of the ANIT-treated rats was significantly greater than the control rats ($p<0.02$). No significant difference was found between control and ANIT-treated rats for mean liver weights and biliary capacity with ANIT treatment was not accompanied by any change in liver weight or bile flow rate.

3638 ROLE OF KUPFFER CELLS AND SUPPRESSOR T CELLS IN THE GRAFT VERSUS HOST REACTION AFTER INTRAHEPATIC LYMPHOID TISSUE IMPLANTATION.

(Eng.) Vuitton, D.; Eloy, R.; Clendinnen, G.; Grenier, J. F. (Unit Surgical Res. and Biophysiopathology of the Intestine, Ave. Moliere, 67200 Strasbourg/Hautepierre, France). *Cell. Immunol.* 34(1):138-145; 1977.

Semiallogeneic lymph nodes were implanted into the livers of August (AgB$_3$) x Lewis (AgB$_1$) rats to study the roles of Kupffer cells and suppressor thymus-derived lymphocytes (T cells) in the immunosuppressive function of the liver during the graft-versus-host (GVH) reaction. In some animals, suppressor T cells were impaired by adult thymectomy 10 weeks before the induction of GVH reaction, and, in others, blockade of Kupffer cells was achieved by the injection of colloidal substrate at the time of antigen recognition; thus the effects of each type of cell on immunosuppressive function of the liver were studied separately. The development of a severe clinical GVH reaction and a near-50% mortality between the 4th and 10th postoperative days among thymectomized rats showed that the protective role played by the liver in the reaction to intrahepatic implantation of semiallogeneic lymphoid tissue is severely impaired by thymectomy 10 weeks prior to implantation. In contrast, impairment of the function of Kupffer cells by gelatin uptake did not result in a lethal GVH reaction. Histological changes observed in the spleen of thymectomized rats included cellular depletion of the white pulp and intense lymphoblastic proliferation in the red pulp 8 days after lymph node implantation. The cellular depletion of white pulp was still present at 15 days after implantation, while the cellular infiltration of the red pulp disappeared almost completely. Postmortem examination on the 6th day after lymph node implantation revealed severe lymphoid atrophy that might be related to the lethal GVH reaction. The results suggest that a subpopulation of the recipient's short-lived T cells is involved in the immunosuppressive function of the intact liver and that Kupffer cells are not an essential component of the protective mechanisms of the liver.

3639 HEPATIC BLOOD FLOW MEASUREMENT.

(Eng.) Nxumalo, J. L.; Teranaka, M.; Schenk, W. G., Jr. (Dept. Surgery, State Univ. New York at Buffalo, Buffalo, NY). *Arch. Surg.* 113(2):169-172; 1978.

A comparison was made between total hepatic blood flow measured by the single injection of indocyanine green (0.5 mg/kg) and the electromagnetic flow methods in the dog, in which circulatory overload was induced by dextran 40 infusion (2.0% of body weight over 30 min). While there was close correlation between the values obtained by the two methods in normal dogs, hepatic blood flow was overestimated by 40-60% by the indirect indocyanine green method following dextran infusion if the electromagnetic method was used as a comparison standard. One possible explanation for the puzzling finding that the total hepatic blood flow as measured by the indocyanine green clearance method was larger than that measured by the electromagnetic flow method may be that there was a decreased extraction ratio after dextran infusion.

3640 BLOOD FLOW IN NORMAL AND CHOLESTATIC DOG LIVER AS MEASURED BY INTRAPARENCHYMAL INJECTION OF XENON 133.

(Eng.) Hall, C.; Bergan, A.; Henriksen, J. E. (Rikshospitalet, Langesgt., Oslo 1, Norway). *Eur. Surg. Res.* 9(5):357-363; 1977.

Parenchymal liver blood flow, as reflected by the washout of intraparenchymally injected ^{133}Xe, was studied at different stages of total cholestasis in the dog over a 3-week period. In three dogs, the gallbladder was removed and the common bile duct was divided between ligatures, resulting in total cholestasis. Three other dogs served as controls. In dogs subjected to total cholestasis, the median parenchymal liver blood flows measured after 1 hr, 7 days, 14 days, and 21 days of cholestasis were 53.2 (range, 40.4-67.5), 51.7 (range, 39.1-57.4), 59.3 (range, 49.2-71.9), and 51.7 (range, 30.3-77.6) ml/min/100 g liver tissue, resp., compared with median flow values in control dogs of 50.4 (range, 39.7-82.0), 41.0 (range, 34.0-54.2), 47.9 (42.9-63.1), and 45.4 (35.9-52.3) ml/min/100 g liver tissue, resp. The differences found between measurements obtained from cholestatic and normal dog livers were not statistically significant at any stage of the experiment. Thus cholestasis does not appear to influence parenchymal liver blood flow in the dog. Histograms of the results obtained from normal and cholestatic and normal dogs were plotted weekly, and it was concluded from these that cholestasis also does not influence the distributive pattern of the obtained flow values. However, the method applied in this experiment does not give information about blood flow through eventual anastomoses or about the relative contribution of the portal venous and the hepatic arterial system to the flow measured. The above results do not agree with most of the previously reported studies on parenchymal liver blood flow. The reason for the disparity may lie primarily in the variety of methods utilized and also in the lack of objective assessment of the actual cholestatic damage induced in different studies at various time intervals.

3641 CORRELATION BETWEEN XENON-133 RECTUM-TO-HEART TIME AND PORTAL VENOUS HEMODYNAMICS.

(Eng.) Ludewig, R. M.; Castell, D. O. (Eastern Virginia Medical Sch., 600 Gresham Drive, Norfolk, VA 23507). *J. Surg. Res.* 24(2):92-96; 1978.

The relationship between portal venous resistance and the time in which ^{133}Xe is transported from the rectum to the heart (RHT) was studied in dogs, to determine whether this marker could be used for evaluating the patency of surgically created portasystemic shunts. The RHT was determined in normal dogs (mean portal venous pressure [PVP]=9.3 cm H_2O), dogs with partially occluded portal veins (mean PVP, 25 cm H_2O), and dogs with totally occluded portal veins (mean PVP, 52 cm H_2O). During each incremental rise in PVP, the ^{133}Xe RHT increased significantly ($p<0.001$). The mean RHT in normal dogs rose from 74 to 250 sec when the portal vein was totally occluded. The results indicate that the ^{133}Xe RHT may be a useful parameter for determining the patency of surgically created portasystemic anastomosis. Further studies will be necessary to determine the effect of naturally occurring portasystemic shunts on the RHT and to support the validity of the test in the presence of developed collaterals.

3642 CLINICAL STUDY OF LIVER BLOOD FLOW IN MAN MEASURED BY ^{133}Xe CLEARANCE AFTER PORTAL VEIN INJECTION. (Eng.) Sherriff, S. B.; Smart, R. C.; Taylor, I. (Sheffield Royal Infirmary, England). *Gut* 18(12):1027-1031; 1977.

Liver blood flow was determined by ^{133}Xe clearance in 14 conscious patients with colorectal cancer, in whom the value of adjuvant liver perfusion of 5-fluorouracil was also being tested. Access to the portal circulation was achieved by dilatation and cannulation of the obliterated umbilical vein. The clearance from the liver of a bolus of ^{133}Xe was monitored using a gamma-ray camera so that blood flow from different areas of the liver could be calculated. The clearance curve of ^{133}Xe was a double exponential of which the initial fast component accounted for a consistently high proportion of the total clearance. The perfusion studies have shown wide differences in blood flow to the various areas of the liver in the same patient, in addition to a wide variation in perfusion rate between the 14 patients. This technique of quantitative estimations of liver blood flow to different areas of the liver may have importance in planning operative procedures and understanding the hemodynamic mechanisms involved in liver disease.

3643 HEPATIC VASCULATURE: A CONCEPTUAL REVIEW. (Eng.) Lautt, W. W. (Coll. Medicine, Univ. Saskatchewan, Saskatoon, Saskatchewan S7N OWO, Canada). *Gastroenterology* 73(5):1163-1169; 1977.

Information concerning the hepatic circulation is reviewed, with emphasis on the role of hepatic blood vessels in hepatic and homeostatic functions. Contrasts are made with resistance, capacitance, and fluid exchange functions in other better known vascular beds. Hemodynamic changes that produce shifts in fluid exchange in other tissues are without effect in the liver. Elevations of hepatic venous pressure are transferred quantitatively to the sinusoids and result in prolonged, massive fluid filtration into the abdominal cavity. Other factors that are involved with control of fluid exchange are discussed. The liver contains a large volume of blood that can be rapidly mobilized during hemorrhage. The hepatic circulation is highly sensitive to changes in circulating blood volume and serves as a major buffer for expanded or contracted blood volume. Control of hepatic blood flow and the reciprocal relationship between portal and hepatic arterial flow is discussed. Changes in hepatic blood flow produce marked changes in hepatic clearance rates of a wide variety of compounds. It is concluded that the hepatic artery is not controlled by local tissue metabolism but rather is controlled by a mechanism that tends to maintain hepatic blood flow (and therefore clearance rates) constant.

3644 THE EFFECT OF HYPERTONIC INFUSIONS ON HEPATIC BLOOD FLOWS AND LIVER VOLUME IN THE CAT. (Eng.) Lautt, W. W.; MacLachlan, T. L.; Brown, L. C. (Coll. Medicine, Univ. Saskatchewan, Saskatoon, Saskatchewan S7N OWO, Canada). *Can. J. Physiol. Pharmacol.* 55(6):1339-1344; 1977.

The effects of i.v. and intraportal infusions of hypertonic NaCl and glucose solutions on the resistance and capacitance vessels were studied in the intact feline liver. All doses infused produced vasodilation of the hepatic artery. A rough estimate would suggest that the tonicity changes equal to those seen after hemorrhage might produce an increase of arterial conductance to no less than 110% and no greater than 140% of control conductance. In response to i.v. infusions, portal flow increased to the same extent as did arterial flows. The resistance vessels were equally affected by equal osmolal loads of glucose or NaCl, but the hepatic volume changes were quite different depending on the substances infused. In marked contrast with the resistance vessel response to hypertonic NaCl, the hepatic capacitance vessels did not dilate. Liver volume decreased. Cessation of the infusion resulted in increases of hepatic volume to above control levels. Glucose produced consistent steady increases in volume that may have been associated with fluid uptake by the hepatocytes in conjunction with glucose uptake.

3645 THE EFFECT OF INCREASED INFERIOR VENA CAVA PRESSURE ON HEPATIC CIRCULATION IN THE DOG. (Eng.) Sugar, I.; Jakab, F.; Szabo, G. (Semmelweis Univ. Medical Sch., Mezo Imre ut 17, H-1430, Hungary). *Res. Exp. Med.* 171(3):263-270; 1977.

The effect of increased inferior vena cava pressure (IVCP) on hepatic circulation was studied in dogs. IVCP was raised by a balloon catheter introduced via the jugular vein. Hepatic artery flow (HAF) and portal venous flow (PVF) were measured with the electromagnetic flow meter. The increase of IVCP uniformly reduced HAF and PVF; the relative contribution of the two vessels to the HBF did not change. The relationship between IVCP increase and HAF reduction and between the decrease of hepatic artery (AP) IVCP and the reduction of HAF was linear. There was no sign of autoregulation or vasomotor regulation of HAF. The changes in IVCP were only partially transmitted to the portal venous pressure (PVP). There was no change in intrahepatic portal resistance with increased IVCP. The increase in PVP did not lead to resistance changes in the splanchnic circulation. As a sign of the autoregulation of splanchnic circulation, the AP-PVP-versus-PVF curve was concave to the pressure axis. As a result of opposing autoregulatory and vasomotor influences in the intact animal, the hepatic circulation appears to react passively to the increased outflow pressure.

3646 COMPARISON OF THE METABOLISM OF CHYLOMICRONS AND CHYLOMICRON REMNANTS BY THE PERFUSED LIVER.

(Eng.) Gardner, R. S.; Mayes, P. A. (Royal Veterinary Coll., London NW1 OTU, England). *Biochem. J.* 170(1):47-55; 1978.

The hepatic metabolism of chylomicrons and chylomicron remnants was compared after adding approximately equal numbers of each lipoprotein particle to the perfusate of isolated rat livers. At least 40% of the added remnants were metabolized by the liver, compared with less than 3% for chylomicrons. There was significantly more net removal of labeled remnants than of chylomicrons by the liver ($p<0.001$). A greater proportion of labeled cholesterol than of labeled triacylglycerol fatty acids was transferred to the liver from each lipoprotein. Cholesteryl esters of remnants were hydrolyzed, and triacylglycerol fatty acids of remnants were oxidized to CO_2 more extensively than those of chylomicrons. There was greater oxidation of remnant glycerolipid [1-^{14}C]oleate than of glycerolipid [1-^{14}C]palmitate. A large fraction of the fatty acids of remnants, but not of chylomicrons, was transferred to phospholipids, which were released by the liver in a lipoprotein of relative density less than 1.006. Label from remnants, but not from chylomicrons, was found in lipoproteins of relative density of over 1.006, which were not released during perfusion but could be flushed out from the liver at the end of perfusion. There are significant qualitative and quantitative differences in the metabolism of chylomicrons and chylomicron remnants.

3647 BILIARY EXCRETION OF SOME ANIONIC DERIVATIVES OF DIETHYLSTILBOESTROL AND PHENOLPHTHALEIN IN THE GUINEA PIG.

(Eng.) Barford, P. A.; Olavesen, A. H.; Curtis, C. G.; Powell, G. M. (Dept. Biochemistry, Univ. Coll., P.O. Box 78, Cardiff CF1 1XL, Wales). *Biochem. J.* 168(3):373-377; 1977.

The metabolic fates and modes of excretion of diethylstilbestrol mono[^{35}S]sulfate and diethylstilbestrol di[^{35}S]sulfate were studied in guinea pigs. Comparative studies were also made with [G-^{3}H]diethylstilbestrol and phenolphthalein di[^{35}S]-sulfate. Diethylstilbestrol di[^{35}S]sulfate (1 mg/0.2 ml water/200 g) was extensively eliminated in the bile unchanged. After the administration of diethylstilbestrol mono[^{35}S]sulfate, extensive biliary elimination of radioactivity was also recorded. Radioactive components were identified as diethylstilbestrol disulfate, diethylstilbestrol monosulfate monoglucuronide, and unchanged diethylstilbestrol monosulfate. When [G-^{3}H]diethylstilbestrol was administered, ^{3}H-labeled diethylstilbestrol monoglucuronide, diethylstilbestrol monosulfate monoglucuronide, and diethylstilbestrol disulfate appeared in the bile. Phenolphthalein di[^{35}S]sulfate was excreted unchanged in bile. These findings are discussed in relation to studies carried out in the rat, and species differences are related to differences in enzyme activities in rat and guinea-pig liver.

3648 ORNITHINE DECARBOXYLASE ACTIVITY AND THE ONSET OF DEOXYRIBONUCLEIC ACID SYNTHESIS IN REGENERATING LIVER.

(Eng.) McGowan, J. A.; Fausto, N. (Div. Biology, Brown Univ., Providence, RI 02912). *Biochem. J.* 170(1):123-127; 1978.

Ornithine decarboxylase activity and polyamine concentrations were measured in regenerating livers of protein-deprived and hypophysectomized male Holtzman rats. Compared with normally fed animals, rats fed on a low-protein diet for 3 days exhibited a considerable delay in DNA synthesis after partial hepatectomy. In the regenerating livers of these animals, the timing of the first peak of ornithine decarboxylase activity was not altered. The second peak of enzyme activity was delayed by a few hours, but polyamine concentrations were similar to those of normally fed rats. The results suggest that, regardless of the possible effect of polyamines on DNA synthesis, the time course of ornithine decarboxylase activity appears to be independent of the onset of DNA replication in regenerating livers.

3649 FATTY ACID SYNTHESIS IN THE REGENERATING LIVER OF THE RAT.

(Eng.) Gove, C. D.; Hems, D. A. (St. George's Hosp. Medical Sch., Cranmer Terrace, London SW17 ORE, England). *Biochem. J.* 170(1):1-8; 1978.

Synthesis *de novo* of fatty acids in the rat liver was measured during regeneration by determining ^{3}H incorporation from ^3H_2O into fatty acids. Fatty acid synthesis, measured per gram of wet weight of tissue, was increased by a factor of about 2 between 1 and 4 days after partial hepatectomy, compared with rates in sham-operated control rat livers. There were no associated changes in the rates of liver cholesterol synthesis or of fatty acid synthesis in adipose tissue in rats after partial hepatectomy, compared with rates in sham-operated rats. In regenerating livers, perfused under three different conditions, there was no alteration in the capacity for fatty acid synthesis compared with that of control rats. The increased synthesis of fatty acids in regenerating liver was associated with insignificant increases in plasma concentrations of triacylglycerols and free fatty acids, with a decrease in content of liver glycogen, and with no change in hepatic activity of acetyl-coenzyme A carboxylase. The accelerated rate of fatty acid synthesis in regenerating liver appears not to be due to any intrinsic alteration in hepatic capacity for fatty acid synthesis, but it may be caused by the continuous action on liver of unidentified circulating factors.

3650 PHOSPHOLIPIDS IN ENDOPLASMIC RETICULUM--THEIR RELATIONSHIP TO DRUG METABOLISM IN EXPERIMENTAL LIVER DISEASE.

(Eng.) Gallenkamp, H. (Medizinische Universitatsklinik, Josef-Schneider-Str. 2, D-8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 24(5):309-316; 1977.

The effect of depletion or accumulation of phospholipids on membrane activity is reviewed, relying upon studies of choline deficiency in rats fed a choline-deficient diet (CDD) as an experimental model. Short-term choline deficiency tended to produce fatty liver and caused a remarkable decrease in phospholipid content in plasma and brain, while the alterations in liver microsomes were less pronounced. Within 24 hr, changes occurred in the floating lipid fraction of the liver homogenate; later, a general reduction of phospholipids, especially phosphatidylcholine, and a slight decrease in phosphatidylethanolamine. The protein content was largely unchanged in the first 5 days, but after 8 and 15 days, there were significant reductions in the microsomal protein content, and the cytochrome P450 content was slightly depressed. During acute (3-week) choline deficiency, the activity of several microsomal drug metabolizing enzymes (e.g., coumarin hydroxylase, hexobarbital oxidase, aminopyrine and ethylmorphine demethylase) decreased. Prolonged choline deficiency (up to 140 days) resulted in a fall of the plasma and brain phospholipid content, while the total microsomal phospholipid content in the liver was unchanged, and drug metabolizing activity was found to be normal both *in vivo* and *in vitro*. It is hypothesized that drug metabolizing activity in isolated microsomes or *in vivo* may depend on a balance of endoplasmic constituents and thus on a normal total phospholipid content and normal distribution of the phospholipid fraction and fatty acids and that imbalances lead to liver disease states. Under conditions of α-naphthyisocyanate-induced cholestasis, UDP-glucuronyl transferase activity was elevated, cytochrome P450 content was lowered, and microsomal protein content was elevated. In galactosamine-induced hepatitis, there was a decrease in cytochrome P450 content, a 2.5-fold increase in phospholipids, a ninefold increase in neutral lipids, and an elevation in the microsomal UDP-glucuronyl transferase activity. The elevation of the latter enzyme in both models of hepatocellular damage can be tentatively explained by an alteration in membrane structure. The role of phospholipids in human liver disease lacks firm proof because there is no information available about content and composition of phospholipids in human liver, so therapeutic use of essential phospholipids is controversial. There seems to be no established correlation between phospholipid content in liver disease and *in vivo* activity of drug-metabolizing enzymes.

3651 CHANGES IN RAT SERUM LIPOPROTEINS FOLLOWING LIGATION OF THE BILE DUCT.

(Eng.) Hinton, R. H.; Mullock, B. M. (Wolfson Bioanalytical Center, Univ. Surrey, Guildford, Surrey GU2 5XH, England). *Clin. Chim. Acta* 82(1/2):31-44; 1978.

The serum lipoproteins of normal and of cholestatic rats were studied by crossed immunoelectrophoresis coupled with separations by rate and isopycnic density gradient centrifugation and by gel exclusion chromatography. Normal rat serum contained distinct lipoprotein species closely analogous to human very low density lipoprotein, low density lipoprotein, low density component of high density lipoprotein, and high density component of high density lipoprotein (VLDL, LDL, HDL_2, and HDL_3, resp.). Three days after common bile duct ligation, there were major changes in the lipoproteins of rat serum. The amounts of VLDL, LDL, and of a minor HDL component were elevated, and several novel types of lipoprotein were detected. Three of these were identified as the characteristic lipoprotein of cholestasis, lipoprotein x, as an enlarged and modified HDL, and as a lipoprotein of density 1.055 g/ml intermediate in size between LDL and VLDL. Some unusually small VLDL particles were also detected. It is concluded that the changes in rat serum lipoproteins following common bile duct ligation are very similar to the changes observed in cholestatic disease in human patients.

3652 MECHANISM OF SECRETION OF BILIARY LIPIDS: ROLE OF A MICROTUBULAR SYSTEM IN HEPATOCELLULAR TRANSPORT OF BILIARY LIPIDS IN THE RAT.

(Eng.) Gregory, D. H.; Vlahcevic, Z. R.; Prugh, N. F.; Swell, L. (Veterans Admin. Hosp., Richmond, VA 23249). *Gastroenterology* 74(1):93-100; 1978.

The role of microtubules in the hepatocellular transport of biliary lipids was investigated, using the actively secreting isolated rat liver perfusion model and the microtubular blocking agents, vinblastine and colchicine. The liver was perfused with sodium taurocholate (12 μmol/hr) to produce active lipid secretion for 90 min before vinblastine administration and for 60 min before colchicine. The vinblastine- and colchicine-treated livers were then perfused for an additional 60 and 120 min, resp. Control groups received isotonic saline. Specific and nonspecific hepatic metabolic functions, including perfusion flow rates, protein and lecithin synthesis, bile acid uptake, and cytidine diphosphate choline 1,2-diglyceride transferase activity were not significantly altered by vinblastine (1×10^{-5} M or 5×10^{-5} M). Similarly, colchicine administration (5×10^{-6} M) had no effect on flow rates, protein synthesis, biliary lecithin metabolism, oxygen consumption, and β-hydroxybutyrate perfusate concentrations; colchicine did depress perfusate acetoacetate concentration by 33%. These viability criteria validate the metabolic integrity of this model for studying biliary lipid transport. Biliary lipid secretion and bile flow were significantly inhibited by both blocking agents at all concentrations. The selective effect on phospholipid and cholesterol output, however, was greater than for either bile acids or flow. These data support the concept that biliary lipids are secreted by a heterogeneous and complex transport process and also provide definitive evidence that the hepatocyte microtubular network participates in the translocation of lipids from microsomes to the canalicular membrane.

3653 HEPATIC METABOLISM OF MEDIUM CHAIN TRIGLYCERIDES. (Eng.) Bach, A.; Debry, G.; Metais, P. (Hopital Civil, Strasbourg, France). *Bibl. Nutr. Dieta* (25):24-35; 1977.

The hepatic metabolism of medium-chain triglycerides (glycerol esters whose fatty acids contain between 6 and 12 carbon atoms) is reviewed. Medium-chain triglycerides are only slightly integrated into the hepatic lipids (octanoic acid is 6-18 times less incorporated into hepatic lipids by rat liver slices than is palmitic acid) and are mostly oxidized. This oxidation strongly activates ketogenesis and leads to a considerable rise in the redox potential in hepatocytes. After their ingestion, medium-chain triglycerides are hydrolyzed completely into fatty acids and their intestinal absorption is more complete and more rapid than that of long-chain triglycerides. Also, medium-chain triglycerides rely much less on the intestinal concentration of bile and pancreatic lipase than do long-chain triglycerides. The present utilization of medium-chain triglycerides principally concerns malabsorption syndromes, irrespective of whether the cause is surgical or medical or whether the origin is digestive, biliary, or pancreatic. The use of medium-chain triglycerides is contraindicated in all states of acidosis.

3654 BILE COMPOSITION IN RELATION TO RACE AND DIET: STUDIES IN RHODESIAN AFRICANS AND BRITISH SUBJECTS. (Eng.) Heaton, K. W.; Wicks, A. C. B.; Yeates, J. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (University Park Press: Baltimore, MD): 197-202; 1977.

Differences in the composition of gallbladder bile were investigated in age- and sex-matched groups of urban Britons and urban and rural Africans, and an attempt was made to relate these differences to diet and nutritional status so that an explanation of the differing gallstone prevalence among these groups might be advanced and a clue to the etiology of gallstones obtained. Comparisons were made among three groups of men and between two groups of women: 12 British urban youths, 12 African urban youths, and 11 African rural youths on one hand and 12 British urban women and 10 African rural women on the other. The data collected consisted of their height and weight, an assessment by dietary recall of sucrose intake (in Africans only), and analysis of fasting plasma and duodenal bile.
The total concentration of biliary lipids was usually greater in the African youths, averaging twice as high as in the British youths, suggesting that bile is more concentrated in African gallbladders. Pronounced differences were also found in the relative proportions of bile acids, phospholipids, and cholesterol in the bile of Britons and Africans, the values being 72 versus 82%, 24 versus 15.5%, and 4 versus 2.5%, resp. There was no significant difference among the male groups with respect to the relative proportions of cholate and chenodeoxycholate. However, deoxycholate was significantly more abundant in the bile of urban Britons than in that of rural Africans ($p<0.05$) or in that of Africans combined ($p<0.02$), due, perhaps, to the high cereal fiber intake of the African subjects (Rhodesians). In the women, the proportions of cholate, chenodeoxycholate, and deoxycholate were indistinguishable between African and British subjects. But as in the youths, the bile acids were significantly higher ($p<0.01$) and the phospholipid and cholesterol levels significantly lower ($p<0.02$ and $p<0.02$, resp.) in the African women. In both the male and female study groups, the cholesterol saturation index of the bile was not useful in distinguishing the groups. The glycine:taurine conjugation ratio in all the African youths or in the rural African youths alone was significantly higher than in the British youths ($p<0.05$ and $p<0.01$) and significantly higher in the African women than in the British women ($p<0.002$). These differences may also be due to the high fiber content of the Rhodesian diet. No significant relationship was found between the cholesterol saturation of bile and either body fatness (judged by weight relative to height), estimated sucrose intake, relative amount of chenodeoxycholate in bile, or percentage deoxycholate in bile.

3655 DISTRIBUTION OF BILE ACIDS IN RATS. (Eng.) Uchida, K.; Okuno, I.; Takase, H.; Nomura, Y.; Kadowaki, M.; Takeuchi, N. (Shionogi Res. Lab., Fukushima-ku, Osaka 553, Japan). *Lipids* 13(1):42-48; 1978.

The distribution and biliary and fecal excretion of bile acids were examined in male Wistar rats of about 300 g. The bile acid pool size of the rats on ordinary diet was 40 mg/rat, biliary secretion was 14 mg/hr, and fecal excretion was 10 mg/day. Bile acids were mainly located in the small and large intestinal contents (87% and 10%, resp., of the pool), but a portion was found in the intestinal wall and the liver. Rats fed 2% cholesterol-supplemented diet for 1 week showed similar values for pool size and biliary secretion with the rats on ordinary diet, but higher values for fecal excretion and distribution ratio in the large intestinal contents. Cholic acid was a major component in the bile, small intestinal wall, small intestinal content and liver, while the bile acid composition ratios were similar to each other, although a relatively large amount of α-muricholic acid was found in the intestinal wall and liver. Both the wall and content compositions of the large intestine were similar to that of the feces, in which lithocholic, deoxycholic, α- and β-muricholic acids were the main components, although the ratios of α- and β-muricholic acids in the large intestinal wall were larger than those in the intestinal contents or feces. The high concentrations of these bile acids may indicate a difference of transport velocity across the cell membrane.

3656 THE EFFECT OF FEEDING ON THE BILE SALT-INDEPENDENT CANALICULAR SECRETION IN DOGS.

(Eng.) Austin, G. L.; Johnson, S. M.; Shires, G. T., III; Jones, R. S. (Duke Univ. Medical Center, Durham, NC 27710). *Am. J. Surg.* 135(1):36-39; 1978.

The effect of feeding on canalicular secretion was investigated in conscious dogs. Three dogs were prepared by cholecystectomy, ligation of the lesser pancreatic duct, and insertion of cannulas into the duodenum and stomach. Bile was collected by cannulating the common bile duct through the duodenal cannula. Canalicular secretion was estimated by the biliary clearance of erythritol. Feeding caused increased bile flow ($p<0.05$ at 3-4 hr), increased erythritol clearance ($p<0.05$ at 1 and 2 hr after feeding), decreased bile salt concentration ($p<0.05$ at 2 hr), and unchanged bile salt output. These findings indicate that feeding stimulated the bile salt-independent canalicular secretion.

3657 BILE ACID-INDUCED INCREASE IN BILE ACID-INDEPENDENT FLOW AND PLASMA MEMBRANE NaK-ATPase ACTIVITY IN RAT LIVER.

(Eng.) Wannagat, F. J.; Adler, R. D.; Ockner, R. K. (Reginharstr. 30, D-506 Bensberg, W. Germany). *J. Clin. Invest.* 61 (2):297-307; 1978.

The mechanism for the significant increase in bile acid-independent secretion, expressed per mass of secreting parenchyma and seen in the livers of both selectively obstructed and bile acid-loaded rats, was investigated. Relative to controls, bile acid-independent flow per gram of nonobstructed liver was increased approximately threefold in selectively obstructed rats and 43% in bile acid-loaded rats with normal ducts. In rats infused with bile acids at similar rates for only 16 hr, no increase was observed. Studies with $[^{14}C]$erythritol suggest that the increased bile flow under these conditions was of canalicular origin. NaK-ATPase activity in canaliculi-enriched liver plasma membrane preparations from the nonobstructed lobes of selectively obstructed rats and from 48-hr bile acid-loaded rats was increased by 47% and 52%, resp., relative to controls, but was not increased in membranes from 16-hr bile acid-loaded rats. Canalicular membrane 5'-nucleotidase and Mg ATPase activities also were increased. These studies show that augmented bile acid flux through secreting liver causes an adaptive increase in bile acid-"independent" flow and in the activity of canalicular membrane enzymes. The mechanism by which bile acids modulate this and previously reported aspects of bile secretion remains to be elucidated.

3658 DEPENDENCE OF THE BILIARY EXCRETION OF IOPANOIC ACID ON BILE SALTS.

(Eng.) Loeb, P. M.; Barnhart, J. L.; Berk, R. N. (Presbyterian Hosp., 8200 Walnut Hill Lane, Dallas, TX 75231). *Gastroenterology* 74(2, Part 1):174-181; 1978.

The extent to which iopanoate excretion in bile is dependent upon bile salt excretion was investigated in unanesthetized dogs with bile fistula. The biliary excretion of iopanoate was studied at four different rates of bile salt excretion in separate experiments produced by interruption of the enterohepatic circulation without bile salt infusion and by infusing sodium taurocholate at three constant rates (0.48, 1.87, and 3.21 µmol/min/kg). Iopanoic acid was infused in stepwise increasing rates in each of the four groups of experiments. The maximum excretion of iopanoate into bile (E_{max}) was derived from a computer fit of the relation between the biliary excretion rate and plasma concentration of iopanoate for each of the four rates of bile salt excretion. The calculated E_{max} was closely linked to the rate of bile salt excretion. The E_{max} increased in an apparent linear manner from 0.20 to 2.36 µmol/min/kg as the rate of bile salt excretion increased from 0.21 to 2.62 µmol/min/kg. From the slope of the relation between the biliary excretion of bile salts and the E_{max} of iopanoate, it was determined that 0.89 µmol of iopanoate was coupled with each µmol of bile salt. However, at low plasma concentrations of iopanoate (<0.06 µmol/ml), when maximum transport of the compound was not obtained, increasing rates of taurocholate infusion did not affect the biliary excretion of iopanoate. If these data in dogs can be extrapolated to man, the enhancement of the biliary excretion of iopanoate by bile salts indicates the importance of maintaining the enterohepatic circulation of bile salts during the biliary excretion phase of cholecystography with iopanoic acid.

3659 ERYTHRITOL AND MANNITOL CLEARANCES WITH TAUROCHOLATE AND SECRETIN-INDUCED CHOLERESES.

(Eng.) Barnhart, J. L.; Combes, B. (Univ. Texas Southwestern Medical Sch., Dallas, TX 75235). *Am. J. Physiol.* 234(2):E146-E156; 1978.

To determine whether erythritol and mannitol enter bile during secretin-induced choleresis, the biliary clearances of ^{14}C-erythritol (C_{ery}) and ^{3}H-mannitol (C_{mann}) were measured simultaneously in dogs during choleresis induced by sodium taurocholate and by secretin. C_{ery} increased equally with the increase in bile flow induced by taurocholate, whereas mannitol entry into bile was partially restricted; the change in $(\Delta)C_{ery}/\Delta$bile flow averaged 0.96; $\Delta C_{mann}/\Delta C_{ery}$ averaged 0.81. Values for erythritol clearance exceeded bile flow by a constant volume over a wide range of bile flow readings, which suggests distal reabsorption of a fixed amount of fluid, independent of canalicular bile production. During secretin-induced choleresis, both C_{ery} and C_{mann} accompanied 30-40% of the increase in bile flow, and the C_{mann}/C_{ery} ratio was 1.02. Thus, the secretin-responsive region is permeable to both erythritol and mannitol. This fact affects the extent to which measured erythritol clearance accurately reflects canalicular bile formation; C_{ery} may underestimate or overestimate canalicular bile flow. The electrolyte composition of bile remained relatively constant over a broad range of bile flow samplings although the characteristics of taurocholate- and secretin-induced biles differed from each other.

Taurocholate-stimulated bile was virtually isotonic. Secretin-induced bile had a high total concentration of electrolyte (mean concentration 367 mEq/l) rich in chloride and bicarbonate and was hypertonic.

3660 EFFECT OF BILIARY OBSTRUCTION ON 26-HYDROXYLATION OF C_{27}-STEROIDS IN BILE ACID SYNTHESIS. (Eng.) Gustafsson, J. (Karolinska Institutet, Stockholm, Sweden). *J. Lipid Res.* 19 (2):237-243; 1978.

The effect of biliary obstruction on side chain hydroxylations in the biosynthesis and metabolism of bile acids was studied in male Sprague-Dawley rats. For comparison, several other hydroxylation reactions in bile acid biosynthesis and metabolism were assayed. Biliary obstruction inhibited microsomal 26-hydroxylation of 5β-cholestane-3α,7α-diol and microsomal 25- and 26-hydroxylation of 5β-cholestane-3α,7α,12α-triol. Microsomal 7α-hydroxylation of cholesterol and 6β-hydroxylation of lithocholic acid increased markedly, whereas the increase in microsomal 12α-hydroxylation of 5β-cholestane-3α,7α-diol was less. Mitochondrial 26-hydroxylation of cholesterol, 5-cholestene-3β,7α-diol, and 7α-hydroxy-4-cholesten-3-one was stimulated, whereas 26-hydroxylation of 5β-cholestane-3α,7α-diol was not affected and that of 5β-cholestane-3α,7α,12α-triol was markedly inhibited. The results indicate that mitochondrial 26-hydroxylation, particularly of substrates that are primarily precursors of chenodeoxycholic acid, plays a more important role in bile acid biosynthesis under conditions of biliary obstruction than under normal conditions.

3661 OCCURRENCE OF SULFATED 5α-CHOLANOATES IN RAT BILE. (Eng.) Eriksson, H.; Taylor, W.; Sjovall, J. (Karolinska Inst., Stockholm, Sweden). *J. Lipid Res.* 19(2):177-186; 1978.

Bile acids in bile from male and female Sprague-Dawley rats with cannulated bile ducts were analyzed by repetitive scanning gas-liquid chromatography-mass spectrometry after initial fractionation of conjugate classes on diethylaminohydroxypropyl Sephadex LH-20. The proportion of total bile acids excreted as sulfates was higher in female (0.9-1.3%) than in male (0.1-0.2%) rats. Most of the sulfated bile acids had a 5α-configuration, allochenodeoxycholic acid being the major compound in bile from female rats. This bile acid was also present in the nonsulfate fraction but could not be found in bile from male rats. The results indicate that gas-liquid chromatography-mass spectrometry must be used to provide sufficient specificity in bile acid analyses. Thus, compounds from the sulfate fraction having the retention times of cholic and chenodeoxycholic acid derivatives are found to be due to derivatives of the 3β,5α-isomers of these bile acids.

3662 SUITABILITY OF [11,12-$^{3}H_{2}$]CHENODEOXYCHOLIC ACID AND [11,12-$^{3}H_{2}$]LITHOCHOLIC ACID FOR ISOTOPE DILUTION STUDIES OF BILE ACID METABOLISM IN MAN. (Eng.) Ng, P. Y.; Allan, R. N.; Hofmann, A. F. (Mayo Foundation and Medical Sch., Rochester, MN 55901). *J. Lipid Res.* 18(6):753-758; 1977.

The stability of the label in [11,12-$^{3}H_{2}$]chenodeoxycholic acid and [11,12-$^{3}H_{2}$]lithocholic acid during enterohepatic cycling was assessed to define the suitability of these tracers for isotope dilution studies of bile acids in man. [11,12-$^{3}H_{2}$]chenodeoxycholic acid (60 μCi) and [24-^{14}C]chenodeoxycholic acid (20 μCi) were administered simultaneously to six healthy adults. The $^{3}H/^{14}C$ ratio of biliary chenodeoxycholic acid and the specific activity of biliary chenodeoxycholic acid were determined to permit calculation of pool size and turnover rate. Urinary label excretion was measured as well as the $^{3}H/^{14}C$ ratio of fecal bile acids. Similar studies were carried out with [11,12-$^{3}H_{2}$]lithocholic acid and [24-^{14}C]lithocholic acid. With [11,12-$^{3}H_{2}$]chenodeoxycholic acid, 10-15% of the label was lost during the first 24 hr, after which the $^{3}H/^{14}C$ ratio of biliary chenodeoxycholic acid remained constant. The loss of ^{3}H caused a consistent overestimate of pool size by 10-15%, but since the fractional turnover rate of the two isotopes was identical, the calculated rate of synthesis was 10-15% greater when determined using ^{3}H. The loss of ^{3}H was attributed to the presence of ^{3}H in positions other than 11 and 12 occurring during the labeling procedure when the unsaturated precursor was exposed to carrier-free tritium gas. The $^{3}H/^{14}C$ ratio of feces was consistently below that of bile, suggesting bacterial removal of additional ^{3}H during distal intestinal passage. In contrast, [11,12-$^{3}H_{2}$]-lithocholic acid lost ^{3}H continuously, so that by 2 days after administration, the $^{3}H/^{14}C$ ratio had fallen to nearly half of that of the administered mixture. It is concluded that isotope dilution studies may be carried out with one preparation of [11,12-$^{3}H_{2}$]chenodeoxycholic acid with an error of 10-15%; possibly a more stable preparation can be made with a gentler tritiation procedure. One preparation of [11,12-$^{3}H_{2}$]lithocholic acid was unsatisfactory for isotope dilution studies in man.

3663 COMPARATIVE EFFECTS OF URSODEOXYCHOLIC ACID AND CHENODEOXYCHOLIC ACID IN THE RHESUS MONKEY: BIOCHEMICAL AND ULTRASTRUCTURAL STUDIES. (Eng.) Fedorowski, T.; Salen, G.; Zaki, F. G.; Shefer, S.; Mosbach, E. H. (Veterans Admin. Hosp., East Orange, NJ 07019). *Gastroenterology* 74(1):75-80; 1978.

To investigate the effects of bile acid feeding on hepatic function, rhesus monkeys were treated with 40 and 100 mg/kg/day of ursodeoxycholic acid (UDCA, 3α,7β-dihydroxycholanoic acid) and chenodeoxycholic acid (CDCA, 3α,7α-dihydroxycholanoic acid), resp. Serum liver enzyme levels were measured at the start of the studies, at monthly intervals thereafter, and terminally. After 6 months, all animals were killed, and the hepatic morphology was examined by light and electron microscopy; biliary bile acid composition and fecal bile composition were determined by gas-liquid chromatography. Liver damage developed in the CDCA-treated animals and consisted of bile duct proliferation, periportal inflammation, fibrosis, and disruption of bile canaliculi, and was associated with a 4- to 10-fold rise in serum transaminase and leucine aminopeptidase levels. Biliary lithocholic acid rose to 10% of the total biliary bile acids in the CDCA-treated animals. In contrast, liver morphology and liver function tests (SGOT, SGPT, and leucine aminopeptidase) were not affected by either 40 or 100 mg/kg/day of UDCA; biliary lithocholic acid concentrations did not change appreciably. Hepatic β-hydroxy-β-methylglutaryl coenzyme A reductase activity (reflecting cholesterogenesis) was suppressed equally (30%) by UDCA and CDCA, but serum cholesterol levels did not change. These findings confirm that CDCA is associated with serious liver damage that probably results from increased formation of lithocholic acid. In contrast, UDCA caused no liver toxicity and no rise in lithocholic acid. Thus, the 7β-hydroxy group of UDCA was apparently degraded differently than the 7α-hydroxy group of CDCA, suggesting that intestinal bacterial dehydroxylases are stereospecific. Because of different bacterial degradation, gallstone treatment with UDCA may be safer and more economical.

3664 STIMULATION OF THYMIDINE INCORPORATION IN MOUSE LIVER AND BILIARY TRACT EPITHELIUM BY LITHOCHOLATE AND DEOXYCHOLATE. (Eng.) Bagheri, S. A.; Bolt, M. G.; Boyer, J. L.; Palmer, R. H. (Franklin McLean Memorial Res. Inst., Univ. Chicago, Chicago, IL). *Gastroenterology* 74(2, Part 1):188-192; 1978.

The early effects of lithocholate and related bile salts on the liver and biliary tract were investigated in female mice by measuring tritiated thymidine (^{3}HTdR) incorporation into DNA after single p.o. doses of bile salts. Lithocholate (≥12.5 mg) enhanced incorporation of ^{3}HTdR at 28 and 36 hr in gallbladder epithelium and at 36 hr in hepatocytes. Areas of hepatocellular necrosis, resembling the lesions of peliosis hepatis, occurred with 12.5- and 25-mg doses of lithocholate, but were not seen with deoxycholate, cholate, chenodeoxycholate, ursodeoxycholate, or hyodeoxycholate. Deoxycholate, and to a lesser extent cholate, also stimulated ^{3}HTdR incorporation in both liver and gallbladder, but chenodeoxycholate did not. These studies suggest that certain bile acids rapidly exert major effects on cell kinetics in the liver and biliary tract, and that these effects depend on the structure of the bile acid molecule. Bile duct (organ) hyperplasia induced by lithocholate must depend on additional factors. The stimulation of proliferative activity by certain (particularly secondary) bile acids may have important consequences for tissues and organs exposed to the bile acid pool during its enterohepatic circulation and subsequent excretion via the colon.

3665 METABOLISM OF URSODEOXYCHOLIC ACID IN MAN. (Eng.) Fedorowski, T.; Salen, G.; Colallilo, A.; Tint, G. S.; Mosbach, E. H.; Hall, J. C. (Veterans Admin. Hosp., East Orange, NJ 07019). *Gastroenterology* 73(5):1131-1137; 1977.

Ursodeoxycholic acid metabolism was investigated in seven subjects during treatment with ursodeoxycholic acid (1 g/day) and chenodeoxycholic acid (1 g/day) for 2 weeks. The molar proportions of biliary cholesterol, lecithin, and bile salts were determined before and during bile acid treatment, and the pool sizes and daily turnover of ursodeoxycholic acid were measured by isotope dilution techniques after the administration of [24-^{14}C]ursodeoxycholic acid. Ursodeoxycholic acid became the major biliary bile acid (56%) during ursodeoxycholic acid treatment, while the proportion of chenodeoxycholic acid declined from 32% to 18% and of cholic acid from 38% to 17%. Deoxycholic acid and lithocholic acid were virtually absent from the bile. During chenodeoxycholic acid administration, chenodeoxycholic acid became the major biliary bile acid (59%), cholic acid declined to 22% of the biliary bile acids, and the proportion of lithocholic acid rose from 1.3% to 3.4%, and an additional 4% were sulfated. Ursodeoxycholic acid increased to 8% of the total bile acids. The molar percentage of biliary cholesterol decreased from 8% to 5% during both ursodeoxycholic acid and chenodeoxycholic acid administration. After [24-^{14}C]ursodeoxycholic acid was administered i.v., the biliary specific activity time curves of ursodeoxycholic acid decayed exponentially during both bile acid treatment periods. In the ursodeoxycholic acid-treated subjects, the ursodeoxycholic acid decay curve intersected with the rising specific activity curve of chenodeoxycholic acid and revealed a precursor-product relationship. The average ursodeoxycholic acid pool measured 938 ± 458 mg with a daily production rate of 900 ± 438 mg/day (absorption). The average ursodeoxycholic acid pool during chenodeoxycholic acid treatment measured 123 ± 82 mg, and the production rate was 91 ± 35 mg/day (synthesis). These studies demonstrate that substantial quantities of ursodeoxycholic acid are absorbed when this bile acid is fed or are synthesized when chenodeoxycholic acid is given. The reduction in bile lithogenicity during ursodeoxycholic acid administration implies that this bile acid, like chenodeoxycholic acid, may be effective in dissolving cholesterol gallstones in man.

3666 HEPATIC ACCUMULATION AND INTRACELLULAR BINDING OF CONJUGATED BILIRUBIN. (Eng.) Wolkoff, A. W.; Ketley, J. N.; Waggoner, J. G.; Berk, P. D.; Jakoby, W. B. (Albert Einstein Coll. Medicine, Bronx, NY). *J. Clin. Invest.* 61(1):142-149; 1978.

Hepatic accumulation and intracellular binding of conjugated bilirubin were studied in Sprague-Dawley and Wistar R rats. After the i.v. injection of unconjugated ^{3}H-bilirubin into normal rats, radiolabeled bile pigments rapidly accumulated in the liver. By 1.5 min after injection, an average of 36% of the injected isotope was present in liver homogenates. Between 3 and 15 min, 37-64% of the total intrahepatic radiolabeled bilirubin was conjugated, as demonstrated by extraction of label into the polar phase of a solvent partition system. This indicates both rapid conjugation and accumulation of conjugated bilirubin within the liver cell. Fluorometric determination of the dissociation constants of purified bilirubin and its mono- and di-glucuronides for homogeneous preparations of two human and four rat glutathione S-transferases, including ligandin, revealed avid binding of all three bile pigments to this class of proteins. Hence, the observation that the intrahepatic bile pigment pool contains substantial amounts of conjugated bilirubin can be attributed to the high binding affinities observed. Thin-layer chromatographic analysis of the ^{3}H-pigments produced by *p*-iodoaniline diazotization of homogenates and cytosol demonstrated that the intrahepatic pool of conjugated bilirubin was almost exclusively monoglucuronide. Examination of radiolabeled bilirubin conjugates excreted in bile during the first 20 min after injection of ^{3}H-bilirubin showed no preferential excretion of diglucuronide. These studies indicate that both bilirubin and its monoglucuronide accumulate within the liver cell as ligands with the glutathione S-transferase and that bilirubin diglucuronide does not significantly accumulate within the general intrahepatocellular pool of protein-bound bile pigments. The latter observation is compatible with the formation and excretion of bilirubin diglucuronide directly from the canalicular pool of the liver cell.

3667 CHOLESTEROL GALLSTONES AND BILIARY LIPID METABOLISM IN THE PRIMATE. (Eng.) Redinger, R. N.; Grace, D. M. (Univ. Hosp., Univ. Western Ontario, London, Ontario N6A 5A5, Canada). *Gastroenterology* 74(2, Part 1):201-204; 1978.

A primate model for the study of cholesterol gallstones is described. Bile became supersaturated with cholesterol in seven female adult baboons with exteriorized enterohepatic circulations during cholestyramine treatment (0.2 g/kg/day, intraduodenally). Cholestyramine decreased bile acid pool size (1.38 ± 0.7 to 0.45 ± 0.02 mmol, $p<0.001$) and secretion rate (12.7 ± 0.9 to 5.6 ± 0.5 mmol/24 hr), while cholesterol secretion remained unaltered. Although biliary lipid and bile acid composition were similarly affected by treatment in both cholecystectomized and intact animals, cholesterol stones formed only in the latter. Thus metabolic alterations in biliary lipid metabolism as well as the presence of the gallbladder were necessary for stone formation.

3668 EVIDENCE FOR A COMMON HEPATIC CHOLESTEROL PRECURSOR SITE FOR CHOLIC AND CHENODEOXYCHOLIC ACID SYNTHESIS IN MAN. (Eng.) Schwartz, C. C.; Vlahcevic, Z. R.; Halloran, L. G.; Nisman, R.; Swell, L. (Veterans Admin. Hosp., Richmond, VA 23249). *Proc. Soc. Exp. Biol. Med.* 156(2):261-264; 1977.

The question of whether cholic and chenodeoxycholic acids arise from a specific cholesterol precursor site in man was investigated in patients with bile fistulae. The patients received ^{14}C-cholesterol and labeled mevalonic acid by constant infusion (for 5 hr) or by i.v. pulse. Bile was collected at 20- to 60-min intervals for 4 hr following the administration of the labeled compounds, and then at longer intervals up to 24 hr. The specific activities of newly synthesized cholic and chenodeoxycholic acids were virtually identical at all time periods. These observations provide evidence for the presence of a common cholesterol substrate pool for primary bile acid synthesis in man. Both cholic and chenodeoxycholic acids appear to be synthesized via the 7α-hydroxycholesterol pathway.

3669 DYNAMICS OF CHOLESTEROL GALLSTONE DISSOLUTION IN CANINE BILE. (Eng.) Thurston, O. G. (Dept. Surgery, Univ. Alberta, Edmonton, Alberta, Canada). *J. Surg. Res.* 24(1):15-19; 1978.

Studies on the dynamics of cholesterol gallstone dissolution in canine bile were carried out using human gallstones. Two cholesterol gallstones, matched for size and gross morphology, were obtained from each of seven patients undergoing cholecystectomy. The cholesterol content of one stone was determined. The second stone was dried, weighed, and measured, and its surface area was calculated. The second stone was then implanted singly into a dog's gallbladder for 21-24 days. The rate of stone dissolution, the effects of stone size and cholesterol content on dissolution rate, and the effect of dissolution on biliary lipids were studied. The rate of stone dissolution varied from 6.9 to 37.9 μg/day/mm^2 and was dependent upon initial surface area of the stone and, to a lesser extent, on cholesterol content of the matched stone. The rate of dissolution declined with the largest stones, suggesting that bile displacement from the gallbladder was a factor. The molar percentage of cholesterol in gallbladder bile increased during the period of dissolution, indicating that gallstones themselves may influence biliary lipid composition.

3670 THE RELATIONSHIP OF CHOLECYSTECTOMY AND TAUROCHOLIC ACID FEEDING TO BILE COMPOSITION AND HEPATOCYTE FUNCTION IN PRAIRIE DOGS. (Eng.) Gardner, B.; Chenouda, M.; Dennis, C.; Patti, J. (Downstate Medical Center, State Univ. New York, 450 Clarkson Ave., Brooklyn, NY 11203). *Am. J. Surg.* 135(1):40-47; 1978.

The prairie dog was used as a model for human gallstone formation. Serum cholesterol was measured at intervals in animals on the lithogenic diet for a period up to 1 yr. Bile collections were made over 24 hr at 1-hr intervals up to 10 hr, and then the remaining 14-hr collection was pooled. Stones formed in the gallbladder of all animals on a lithogenic diet. Hepatic bile was nonlithogenic, whereas gallbladder bile promoted cholesterol precipitation. The addition of taurocholate (2 g/100 ml, 3-4 months) to the lithogenic diet reduced the number of stones and lithogenicity. Cholecystectomy resulted in an increased bile flow and reduced secretion of cholesterol in the animals on a high cholesterol diet. Reduction of cholesterol and bile acid synthesis by negative feedback was demonstrated in isolated hepatocyte culture. The shift of bile salt production to chenodeoxycholates on a high cholesterol intake was demonstrated both *in vivo* and *in vitro*. A theory of gallstone formation is presented that hypothesizes a defect in hepatocyte storage of cholesterol rather than bile acid synthesis as the primary effect, relegating the problem to one of a disease of lipid metabolism.

3671 EFFECT OF AUTOCLAVING OF A LACTOSE-CONTAINING DIET ON CHOLESTEROL AND BILE ACID METABOLISM OF CONVENTIONAL AND GERM-FREE RATS. (Eng.) Wostmann, B. S.; Beaver, M.; Chang, L.; Madsen, D. (Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN 46556). *Am. J. Clin. Nutr.* 30(2): 1999-2005; 1977.

Studies were carried out in conventional and germ-free male Lobund-Wistar rats to determine whether lactose fed at levels usually consumed by the adult population of developed countries could influence cholesterol and bile acid metabolism to a major extent. Feeding lactose in amounts comparable to the adult human intake (6% of diet, and in later studies 10%) had no major effect on the cholesterol and bile acid metabolism of germ-free and conventional rats. However, when lactose-containing casein-starch diets were sterilized by autoclaving, changes in intestinal and/or fecal bile acids were found. Both germ-free and conventional rats demonstrated some increase in intestinal β-muricholic acid concentrations ascribable to the mere presence of lactose in the diet. Autoclaving the diet produced additional changes, especially in the fecal bile acid pattern of conventional rats; the ratio between the β-muricholic-derived secondary bile acids hyodeoxycholic and ω-muricholic acids changed from the usual 5:3 to approximately 1:10, with ω-muricholic acid becoming the major fecal bile acid. These changes point to a notable effect of lactose-derived products, formed during steam sterilization, on the microbial modification of intestinal bile acids in the lower gut.

3672 THE EFFECT OF CALCIUM ON THE OXIDATION OF ACETALDEHYDE BY RAT LIVER MITOCHONDRIA. (Eng.) Cederbaum, A. I. (Mount Sinai Sch. Medicine of the City Univ. New York, New York, NY 10029). *Life Sci.* 22(1):111-125; 1978.

The influence of Ca^{2+} and the cationic environment on the oxidation of acetaldehyde by liver isolated rat mitochondria was studied. Oxidation of acetaldehyde proceeded at different rates under three different conditions: state 4<state 3<valinomycin. Ca^{2+} (>0.10 mM) inhibited the oxidation of acetaldehyde by the isolated mitochondria under all conditions. Valinomycin-stimulated oxidation of acetaldehyde was more sensitive to inhibition by Ca^{2+} than were the state 3 or 4 rates of acetaldehyde oxidation. Acetaldehyde could support an energy-dependent uptake of Ca^{2+} at rates about 20% of that found with succinate. Ruthenium red almost completely prevented the inhibition by Ca^{2+} under all conditions. The addition of externally added NAD^{+} or NADH provided complete relief against the inhibitions by Ca^{2+} of the state 4 and 3 rates of acetaldehyde oxidation. Although some relief was also observed with the valinomycin-stimulated system, significant inhibition persisted. Cations such as Zn^{2+}, Cu^{2+}, or Hg^{2+} also inhibited acetaldehyde oxidation, whereas Mg^{2+} and Mn^{2+} were without effect. These cations also blocked glutamate oxidation, and presumably inhibit acetaldehyde oxidation by preventing reoxidation of NADH. The greater sensitivity of the ionophore-stimulated oxidation of acetaldehyde to inhibition by Ca^{2+} may reflect release of intramitochondrial K^{+}, which is known to occur in the presence of Ca^{2+}, suggesting that acetaldehyde oxidation is influenced by the cation environment within the mitochondria.

3673 EVIDENCE THAT ACETALDEHYDE IRREVERSIBLY IMPAIRS GLYCOPROTEIN METABOLISM IN LIVER SLICES. (Eng.) Sorrell, M. F.; Tuma, D. J.; Barak, A. J. (Veterans Admin. Hosp., 4101 Woolworth Ave., Omaha, NB 68105). *Gastroenterology* 73(5):1138-1141; 1977.

The reversibility of acetaldehyde inhibition of glycoprotein synthesis was investigated in Sprague-Dawley rat liver. When liver slices were incubated for 1 hr in a medium containing either 5 mM acetaldehyde or ethanol and then switched to a fresh medium free from acetaldehyde but containing the appropriate radioactive precursors and reincubated for an additional 3 hr, a decreased incorporation of both [^{14}C]glucosamine and [^{14}C]leucine into hepatocellular and secretory proteins was observed. Further studies were carried out comparing the inhibitory effects of ethanol and acetaldehyde on drug metabolism. Higher concentrations of ethanol were necessary to impair aniline hydroxylation when compared to its effect on glycoprotein metabolism. Acetaldehyde did not affect aniline metabolism, suggesting some specificity for its effect on intracellular metabolic functions. These results show that the acetaldehyde-induced inhibition of glycoprotein synthesis is irreversible under these short-term experimental conditions and is not dependent on the physical presence of acetaldehyde in the incubation medium.

3674 THE EFFECTS OF FRUCTOSE AND OTHER SUBSTANCES ON ACETALDEHYDE AND ETHANOL METABOLISM IN THE RAT. (Eng.) Rawat, A. K. (Medical Coll. Ohio, Toledo, OH 43699). *Res. Commun. Chem. Pathol. Pharmacol.* 18(4):665-676; 1977.

The comparative effectiveness of fructose, glucose, sucrose, and alanine in increasing the rates of ethanol and acetaldehyde clearance was tested in male rats. The administration of fructose i.v. was found to be the most effective, followed by alanine, in increasing the rate of blood alcohol clearance; clearance was increased from 55.7 ± 4 μmol/ml/hr to 132.5 ± 14 µmol/ml/hr with fructose and to 120.0 ± 11 µmol/ml/hr with alanine. The administration of any one of the test substances during ethanol metabolism did not result in a significant change in the levels of blood acetaldehyde. Fructose partially prevented the ethanol-mediated changes in the concentration ratios of lactate/pyruvate and β-hydroxybutyrate/acetoacetate. Its administration also resulted in the reversal of acetaldehyde-mediated changes in the liver. The administration of all test substances resulted in an increase in hepatic glucose levels; however, a combination of these substances with ethanol resulted in decreased hepatic glucose levels. The most pronounced effect on glucose was observed when ethanol was given in combination with glucose. During the simultaneous metabolism of fructose and ethanol, hepatic and blood levels of sorbitol increased markedly. Fructose also exerted the most pronounced antiketogenic action. The increased rates of blood alcohol clearance induced by fructose and alanine are exerted at the hepatic level by producing a more oxidized state of the liver; these observations are of special interest in view of the recent trend toward employing fructose for the treatment of acute ethanol intoxication.

3675 COMMON MECHANISM FOR THE ADAPTIVE INCREASE IN HEPATIC ETHANOL AND ACETALDEHYDE METABOLISM DUE TO CHRONIC PRETREATMENT WITH ETHANOL.

(Eng.) Thurman, R. G.; Brentzel, H. J.; McKenna, W. R. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19174). *Adv. Exp. Med. Biol.* 85A:237-245; 1977.

The effect of chronic ethanol pretreatment on acetaldehyde metabolism was investigated in the perfused rat liver, and evidence that supports the involvement of reoxidation of NADH in stimulating ethanol oxidation in ethanol-treated animals is reviewed. Livers from rats pretreated with ethanol for 3-5 weeks utilized ethanol and acetaldehyde at higher rates than did appropriate controls. This adaptive increase in hepatic ethanol and acetaldehyde uptake was associated with marked (>60%) increase in hepatic oxygen uptake. Ethanol uptake in both ethanol-treated and control livers was similarly sensitive to inhibition by 4-methylpyrazole, rotenone, and antimycin A. The adaptive increase in ethanol uptake was apparently specifically abolished by ouabain. These data are consistent with the hypothesis that chronic treatment with ethanol increases ATPase activity. The ADP produced from these initiating events enters the mitochondrial space and stimulates electron transport and oxygen uptake. As a consequence of these events, a greater rate of NADH reoxidation occurs, resulting in a greater rate of production of NAD$^+$, which stimulates ethanol oxidation via alcohol dehydrogenase and acetaldehyde oxidation via aldehyde dehydrogenase(s).

3676 ETHANOL OXIDATION BY ISOLATED HEPATOCYTES FROM ETHANOL-TREATED AND CONTROL RATS: FACTORS CONTRIBUTING TO THE METABOLIC ADAPTATION AFTER CHRONIC ETHANOL CONSUMPTION.

(Eng.) Cederbaum, A. I.; Dicker, E.; Lieber, C. S.; Rubin, E. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Biochem. Pharmacol.* 27(1): 7-15; 1978.

Various aspects of ethanol oxidation were studied in hepatocytes isolated from rats chronically fed ethanol and from controls to investigate factors contributing to metabolic adaptation after chronic ethanol consumption. Chronic ethanol consumption (36% of total calories for 4 weeks) by rats produced a fatty liver and resulted in a pronounced increase in the rate of ethanol oxidation by isolated hepatocytes. Despite the increase in ethanol oxidation, oxygen consumption with several substrates was not enhanced after chronic ethanol treatment. Ouabain did not abolish the increase in the rate of ethanol oxidation. About 40-50% of the increase in ethanol oxidation persisted after inhibition of alcohol dehydrogenase, mitochondrial oxygen consumption, or the malate-aspartate shuttle. The addition of substrates for the malate-aspartate shuttle slightly increased the rate of ethanol oxidation in hepatocytes from control and ethanol-treated animals. The increased rate of ethanol oxidation was not abolished by the uncoupling agent dinitrophenol, which by itself had little effect on ethanol oxidation. In the presence of aspartate or α-glycerophosphate, dinitrophenol augmented the rate of ethanol oxidation; in the presence of glutamate, the rate of ethanol oxidation was doubled by dinitrophenol. However, the higher rate of ethanol oxidation after ethanol consumption was still found in the presence of various combinations of substrate shuttles, with or without dinitrophenol. Pathways independent of alcohol dehydrogenase may contribute, at least in part, to the increase in ethanol oxidation found after chronic ethanol consumption. It is concluded that ethanol oxidation may be enhanced after chronic ethanol consumption without the establishment of a hypermetabolic state of the liver.

3677 DIFFERENTIAL EFFECT OF ETHANOL INGESTION ON THE PROTEIN SYNTHETIC ACTIVITIES OF FREE AND MEMBRANE-BOUND RIBOSOMES FROM LIVER OF THE WEANLING RAT.

(Eng.) Khawaja, J. A.; Lindholm, D. B. (Dept. Medical Chemistry, Univ. Helsinki, Siltavuorenpenger 10 A, SF-00170 Helsinki 17, Finland). *Res. Commun. Chem. Pathol. Pharmacol.* 19(1): 129-139; 1978.

The influence of chronic ethanol ingestion on the protein synthetic activities of free and membrane-bound ribosomes was studied *in vitro* in the liver of 25-day-old male Sprague-Dawley rats. Ethanol administration (6.3% volume/volume of diet for 13 days) caused about 120% increase in the incorporation of amino acids by free ribosomes. In contrast, membrane-bound ribosomes from the livers of ethanol-fed animals exhibited a 25% decline in their protein synthetic activity. This decline in the activity of membrane-bound ribosomes was abolished after dissolution of membranes by Triton X-100. The observed alterations in protein synthesis due to ethanol intake may be the result of changes in the pH 5 enzyme fraction, an altered amount of ribosome-associated messenger RNA, and damage to the endoplasmic reticulum.

3678 KINETICS OF ETHANOL INHIBITION OF GALACTOSE ELIMINATION IN PERFUSED PIG LIVER.

(Eng.) Keiding, S.; Johansen, S.; Tonnesen, K. (Rigshospitalet, DK-2100 Copenhagen, Denmark). *Scand. J. Clin. Lab. Invest.* 37(6):487-494; 1977.

The effect of ethanol (5-25 mM) on galactose elimination kinetics in the intact liver was studied in the isolated perfused pig liver, using the steady-state infusion technique. Ethanol reduced galactose V_{max} in six experiments to 0.07 mmol/min/kg liver (average) from 0.43 mmol/min/kg obtained in control experiments without ethanol. Also, K_m was significantly reduced from 0.23 mM plasma water to 0.03 mM. Ethanol increased uridine diphosphate (UDP)-galactose 10-fold simultaneous with a rise in the hepatic outflow ratio of lactate to pyruvate to about 300 from 10; this finding indicates that ethanol inhibits epimerase activity. In experiments with increasing galactose elimination rates, the galactose-1-P concentration increased much less than the concentration of galactose, and the phosphorylation of galactose therefore seems to be rate-limiting. *In vitro*, galactokinase activity is inhibited by galactose-1-P. In the present study, ethanol increased galactose-1-P 5-10 times, and the reduction of V_{max} and K_m by ethanol could be explained by uncompetitive inhibition by galactose-1-P with K_i about 0.1 mM. Ethanol decreased UDP-glucose to about 40% and uridine triphosphate to less than 5% probably due to trapping as UDP-galactose. This trapping may depress the forward transferase reaction, and therefore the other cosubstrate galactose-1-P rises and inhibits galactokinase activity.

3679 ETHANOL-INDUCED HYPOGLYCAEMIA IN MAN: ITS SUPPRESSION BY THE ALCOHOL DEHYDROGENASE INHIBITOR 4-METHYLPYRAZOLE.

(Eng.) Salaspuro, M. P.; Pikkarainen, P.; Lindros, K. (Univ. Central Hosp. Helsinki, SF-00290 Helsinki 29, Finland). *Eur. J. Clin. Invest.* 7(6):487-490; 1977.

To examine whether alcohol hypoglycemia can be prevented by 4-methylpyrazole (4-MP) in humans and how this inhibition is related to changes in the redox state of the NAD/NADH couple, the redox state, which reflects the metabolites lactate, pyruvate, 3-hydroxybutyrate, and acetoacetate, was determined from venous blood in 10 healthy subjects. The rate of ethanol elimination and blood concentrations of acetaldehyde were also determined. The infusion of ethanol (0.6 g/kg) caused marked hypoglycemia in subjects fasted for 36 hr. Previous administration of the alcohol dehydrogenase (ADH) inhibitor 4-MP (7 mg/kg, i.v.) strongly suppressed the ethanol-induced hypoglycemia. The rate of ethanol elimination was 84.6 mg/kg/hr. 4-MP caused a 21% reduction of ethanol elimination but had no significant effect on blood acetaldehyde levels. 4-MP also significantly suppressed the ethanol-induced elevation of blood lactate and almost completely prevented the increase in the 3-hydroxybutyrate/acetoacetate ratio, but had only a slight effect on the lactate/pyruvate ratio of venous blood. The results demonstrate that the hypoglycemia and lactacidemia produced by alcohol oxidation can be prevented by a dose of 4-MP that diminishes or prevents the ethanol-induced shift in the NAD-coupled redox state of the liver.

3680 EFFECT OF AMP ON ACUTE CARBON-TETRACHLORIDE HEPATOTOXICITY.

(Eng.) Mikhail, T. H.; Awadallah, R.; Dessoukey, E. A. (Natl. Res. Centre, Dokki, Cairo, Egypt). *Z. Ernaehrungswiss.* 16(4):256-261; 1977.

The protective effect of AMP on carbon tetrachloride (CCl_4) hepatotoxicity was studied in adult albino rats. Rats injected i.p. with 0.5 ml of a CCl_4-mineral oil mixture (1:1 by volume) per 100 g body weight showed significant ($p<0.05$) increases in SGOT (107.4 ± 12.9 versus 69.3 ± 13.0 IU/l for controls), SGPT (152.3 ± 17.7 versus 27.8 ± 7.9 IU/l for controls), alkaline phosphatase (38.9 ± 4.2 versus 16.8 ± 2.9 King-Armstrong U for controls), and total liver lipids (10.99 ± 1.42 versus 4.67 ± .82 g% for controls) and a significant ($p<0.05$) decrease in the albumin/total globulin ratio (0.46 ± .03 versus 0.73 ± .08 for controls). The i.p. administration of 30 mg/rat of AMP 30 min before CCl_4 treatment afforded protection against CCl_4 hepatotoxicity as judged by significantly ($p<0.05$) decreased levels of SGOT (91.2 ± 1.0 IU/l), SGPT (86.0 ± 16.9 IU/l), alkaline phosphatase (19.9 ± 5.7 King-Armstrong U), and total liver lipids (7.80 ± 0.73 g%) and a significantly ($p<0.05$) increased albumin/total globulin ratio (0.59 ± .08). The administration of AMP had no effect on serum total protein. Acute CCl_4 hepatotoxicity produces fatty liver associated with elevations in certain serum enzyme levels and a decrease in the albumin/total globulin ratio. Prior treatment with AMP ameliorates liver function without the complete prevention of fatty liver.

3681 ACTIN-LIKE CONTRACTILE PROTEIN IN CARBON TETRACHLORIDE-INDUCED CIRRHOSIS IN THE RAT.

(Eng.) Toh, B. H.; Cauchi, M. N.; Muller, H. K. (Monash Univ. Medical Sch., Praharan, Victoria 3181, Australia). *Pathology* 9(3):187-194; 1977.

The reactivity of cirrhotic livers with smooth muscle antibody (SMA) was examined, since, in cirrhosis, there is proliferation of hepatocytes and granulation tissue formation with subsequent liver shrinkage. Cryostat sections of livers from rats treated with carbon tetrachloride for 12 weeks were examined by indirect immunofluorescence for reactivity with human serum containing SMA. Increased binding of SMA serum to hepatocytes was observed as early as the first week of CCl_4 treatment and remained enhanced during the 12 weeks of study. No difference in staining intensity was observed between precirrhotic liver parenchymal cells and hepatocytes in regenerative nodules of frankly cirrhotic livers. In addition, granulation tissue fibroblasts in cirrhotic livers showed strong reactivity with SMA serum. The specificity of the staining reaction for actin was established by its prevention on neutralization absorptions of the serum with homogenates of smooth muscle or extracts containing actin derived from smooth muscle. Circulating SMA was not demonstrated in the serum of rats at any phase of the study. The observations show that there is an increased expression of actin-like protein in regenerating hepatocytes and granulation tissue fibroblasts in cirrhotic livers.

3682 CHOLESTATIC STEROID HORMONES INHIBIT TAUROCHOLATE UPTAKE INTO ISOLATED RAT HEPATOCYTES. (Eng.) Schwarz, L. R.; Schwenk, M.; Pfaff, E.; Greim, H. (GSF, Abteilung fur Toxikologie, Gebaude 43, 8042 Neuherberg, W. Germany). *Biochem. Pharmacol.* 26(24):2433-2437; 1977.

The effect of norethandrolone, 17-β-estradiol, and progesterone on hepatocellular uptake and secretion of taurocholate was studied in isolated rat liver cells. The three cholestatic steroids decreased the rate of taurocholate uptake. Norethandrolone inhibited uptake noncompetitively with an inhibition constant (K_i) of 18 μm, but had no effect on the activation energy of uptake. 17-β-Estradiol and progesterone reduced taurocholate uptake by 50% at concentrations between 40 μM and 50 μM. The secretion of taurocholate from taurocholate-loaded cells was slightly increased by all three steroids at concentrations below 100 μM. A 60% inhibition of secretion was observed in the presence of 500 μM norethandrolone. Interference of cholestatic steroids with hepatocellular bile acid uptake may be an important step in the pathogenesis of intrahepatic cholestasis.

3683 STORAGE OF PROTEINS IN THE ROUGH ENDOPLASMIC RETICULUM OF HUMAN HEPATOCYTES IN A PATIENT WITH NORMAL BLOOD PROTEINS, ON ORAL CONTRACEPTIVES. (Eng.) Porte, A.; Batzenschlager, A.; Stoeckel, M. E.; Bockel, R.; Girard, M.; Doffoel, M. (Institut de Physiologie, Strasbourg, France). *Virchows Arch.* [*Pathol. Anat.*] 375(3):241-248; 1977.

The case of a 28-yr-old woman presenting with jaundice and no evident abnormality in α_1-antitrypsin (AAT), in whom protein storage in the rough endoplasmic reticulum of the hepatocytes resembled those in AAT deficiency, is reported. The patient had been taking oral contraceptives for 4 yr. AAT and other blood protein levels were normal. Most hepatocytes contained characteristic globular inclusions, but they were PAS-negative and did not react with anti-AAT antibodies. This storage of protein ceased at the time the jaundice disappeared. Prolonged treatment with high doses of contraceptive steroids may have been involved in this peculiar reaction of the hepatocytes.

3684 MECHANISM OF ESTROGEN-INDUCED SATURATED BILE IN THE HAMSTER. (Eng.) Bonorris, G. G.; Coyne, M. J.; Chung, A.; Schoenfield, L. J. (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *J. Lab. Clin. Med.* 90(6):963-970; 1977.

The effect of ethinyl estradiol (EE) on the biliary saturation index (SI) and on the rate-limiting hepatic enzymes of cholesterol (CH) synthesis and of bile acid (BA) synthesis was studied in male hamsters. The animals received either a standard diet or a standard diet containing EE (50 μg/kg) for 1 month. Biliary lipids were determined at sacrifice. The activities of hepatic microsomal hydroxymethyl glutaryl coenzyme A reductase (HMG-CoAR) and 7α-hydroxylase were assayed. Biliary SI in EE-treated hamsters (1.12 ± 0.04) was significantly greater ($p<0.01$) than in the controls (0.68 ± 0.03). HMG-CoAR activity with EE treatment (299 ± 12.3 pmol/mg/min) was not different from control values (300 ± 9.5 pmol/mg/min). 7α-Hydroxylase activity was less ($p<0.01$) with EE treatment (14.7 ± 1.6 pmol/mg/min) than in the controls (23.0 ± 1.1 pmol/mg/min). EE treatment did not change the amount of esterified CH in total liver tissue from control level (3.92 ± 0.16 μmol/g) or in the microsomal fraction from control level (0.034 ± 0.003 μmol/mg). EE treatment did not change hepatic BA from control values (253 ± 10.4 nmol/g). These studies indicate that the increase in SI associated with EE treatment is associated with inhibition of BA synthesis without effect on CH synthesis. The absence of EE-induced changes in hepatic CH and BA concentrations suggests that this decreased BA synthesis may result from mechanisms other than altered substrate or increased BA feedback.

3685 EFFECT OF ESTRADIOL-17β ON THE METABOLISM OF BILE ACIDS IN THE RAT. (Eng.) Ayaki, Y. (Tottori Univ. Sch. Medicine, Yonago, Tottori 683, Japan). *J. Biochem.* 82(5):1379-1388; 1977.

The effect of estradiol-17β on bile acid metabolism was studied in male rats. A 3-day acute treatment with the hormone (100 μg/100 g, s.c.) caused a decrease in serum cholesterol (from 91.8 ± 7.2 mg/dl in controls to 40.3 ± 7.6 mg/dl) and an increase in hepatic cholesterol (from 1.68 ± 0.05 to 2.62 ± 0.14 mg/g). Chronic treatment with the same quantity twice a week for 3 weeks induced hypercholesteremia (from a control level of 85.3 ± 5.8 to a level of 123.5 ± 9.9 mg/dl), which continued for 10 days after the final dosage, but there was no change in total hepatic cholesterol. Fistula bile from both groups of treated rats collected during 30 min was analyzed for bile acid components. Hyodeoxycholic acid and/or chenodeoxycholic acid increased relative to cholic acid in both groups, as compared with the controls. Kinetic study of the metabolism of bile acids in the chronically treated rats revealed a more than twofold enlargement of the pool size but an almost unchanged half-life of chenodeoxycholic acid. Essentially no change in pool size or half-life was observed for cholic acid. These results indicate that chronic treatment of male rats with estradiol-17β causes an increase in elimination of hepatic cholesterol via the bile acid pathway.

3686 THE EFFECT OF ADMINISTRATION OF ETHINYL ESTRADIOL ON HEPATOCYTE MORPHOLOGY IN THE RHESUS MONKEY.

(Eng.) Wadsworth, P. F.; Kennedy, S. J.; Heywood, R. (Huntingdon Res. Center, Huntington PE18 6ES, England). *Toxicol. Lett.* 1(3): 169-174; 1977.

The effect of ethinyl estradiol administration on hepatic ultrastructure was studied in four female rhesus monkeys. The administration of ethinyl estradiol (100 μg/kg/day) for 26 weeks resulted in elevation of serum alanine aminotransferase (SALT) and serum leucine aminopeptidase values. Light microscopy showed no morphological change, but by transmission electron microscopy, hepatocytes containing needle-shaped electronlucent areas were identified in two of four treated animals, one of which had periportal hepatocytes with intracisternal sequestration of the endoplasmic reticulum. The changes in the hepatocytes were not considered to be sufficient to account for the increased SALT and LAP values. The needle-shaped electronlucent areas seen in the cytoplasm of the few hepatocytes in the two monkeys could possibly represent a cleft remaining after a crystal had been lysed out during processing.

3687 QUALITATIVE ALTERATION IN HEPATIC MICROSOMAL CYTOCHROME P-450 APOPROTEINS ASSOCIATED WITH BILE DUCT LIGATION, AND THE ADMINISTRATION OF ETHINYL ESTRADIOL, PHENOBARBITAL AND 3-METHYLCHOLANTHRENE.

(Eng.) Mackinnon, A. M.; Sutherland, E.; Simon, F. R. (Flinders Medical Center, Bedford Park, South Australia 5042, Australia). *Biochem. Pharmacol.* 27(1):29-35; 1978.

Studies were carried out in livers of Sprague-Dawley rats to investigate whether different forms of cytochrome P-450 are altered in hepatic disorders associated with impaired drug metabolism. Total hepatic cytochrome P-450 was decreased after either bile duct ligation or the administration of ethinyl estradiol (5 mg/kg/day, s.c., 5 days). In contrast, phenobarbital (80 mg/kg/day, i.p., 5 days) increased hepatic content of cytochrome P-450, and when administered with ethinyl estradiol the reduction in cytochrome P-450 was prevented. Microsomal ethylmorphine *N*-demethylase activities paralleled changes in cytochrome P-450 content, except in bile duct ligation, where the activity was diminished to a greater extent. Four forms of microsomal cytochrome P-450 apoproteins, ranging in molecular weight from 50,000 to 58,000 daltons, were tentatively identified in a sodium dodecyl sulfate (SDS)-6 M urea polyacrylamide gel electrophoresis system by their responsiveness to pharmacological agents, turnover, and benzidine peroxidase staining. Phenobarbital administration increased primarily band IV (50,000 daltons); in contrast, only band III (53,000 daltons) was responsive to 3-methylcholanthrene (10 mg/kg/day, i.p., 5 days). Bile duct ligation was associated with a marked reduction in bands I, III, and IV while bands I and III were decreased with ethinyl estradiol administration. Simultaneous administration of phenobarbital and ethinyl estradiol demonstrated a return of band I and an increase in density of bands II and IV. The mechanism of this reversal by phenobarbital was determined by the double-isotope technique, which demonstrated that phenobarbital increases the relative synthesis rates of P-450 apoproteins in ethinyl estradiol-treated rats. These studies support the hypothesis that multiple forms of cytochrome P-450 are present in liver microsomal membranes and that alterations in specific apoproteins may be associated with an increase or a decrease in the functional properties of cytochrome P-450.

3688 ADAPTIVE CHANGES OF RAT LIVER CELLS INDUCED BY REPEATED INTRAPERITONEAL INJECTIONS OF D-GALACTOSAMINE. I. LIGHT MICROSCOPIC, AUTORADIOGRAPHIC AND BIOCHEMICAL STUDIES OF PARENCHYMAL ALTERATION, DNA AND RNA SYNTHESIS.

(Eng.) Schuchhardt, C.; Felgenhauer, K.; Wagner, T. W.; Enzan, H.; Lesch, R. (Dept. Pathology, Univ. Freiburg, Albertstrasse 19, D-7800 Freiburg, W. Germany). *Virchows Arch.* [*Cell Pathol.*] 26(1):43-57; 1977.

To examine the effects of repeated D-galactosamine administration (GalN) on rat livers (i.e., the effects of subacute intoxication), Wistar rats were treated daily with GalN (250 mg/kg) after an initial injection of GalN (375 mg/kg). The interval for this investigation was between 1 hr and 30 days. After the first GalN injection, the light microscopic features of a toxic hepatitis were seen. Following daily repeated GalN injections, the amount of parenchymal necroses as well as the extent of inflammatory infiltration disappeared stepwise, indicating that during this subacute stage of intoxication the reaction pattern of the liver tissue had changed. UDP glucose as well as UDP + UTP trapping was observed 6 hr after a single GalN injection followed by values comparable to those of the controls after eight daily injections. The RNA content per gram of liver did not show any fluctuation after a single or repeated GalN injections. Using ^{3}H-cytidine as a radioactive precursor, however, RNA synthesis during the acute stage of intoxication was shown to be strongly decreased, while the following daily injections led to enhanced RNA synthesis. During the acute stage, the decreased RNA synthesis could be raised to normal values by an additional injection of unlabeled uridine. The DNA content per gram liver did not show any remarkable changes. The incorporation rates of ^{3}H-thymidine were increased three- to fourfold after daily GalN injections. The autoradiographs revealed nearly identical labeling indices of hepatocytes as well as Kupffer cells; these indices were 20- to 30-fold greater than those in controls. The findings indicate important differences between GalN-induced alterations in the acute stage of intoxication and those in the subacute stage following repeated injections. These differences may be explained as an adaptation to repeated GalN intoxication.

3689 AGE DEPENDENT KINETIC STUDIES OF CYTOPLASMIC AND LYSOSOMAL ENZYMES OF THE NORMAL AND D-GALACTOSAMINE INJURED RAT LIVER.

(Eng.) Platt, D.; Forster, K.; Forster, L. (Center Internal Medicine, Justus Liebig-Univ. Giessen, W. Germany). *Mech. Ageing Dev.* 7(3):183-188; 1978.

Studies were carried out in female SIV rats of two age groups (6 weeks and 30 months) to determine if there are age-dependent differences in the development and treatment of galactosamine hepatitis. The rats received (a) a single dose of D-galactosamine (GalN, 600 mg, i.p.) or (b) a single dose of GalN as in (a) plus prednisolone (20 mg/kg, s.c.) at the beginning of the experiment. The kinetic studies disclosed that GalN produced more severe changes in old than in young animals, represented by the activities of cytoplasmic (SGOT and SGPT) and lysosomal (β-acetylglucosaminidase, β-glucuronidase, cathepsin D) enzymes. Prednisolone diminished the morphological liver changes as well as the biochemical disturbances in young rats. There was only a protecting effect in morphological changes of old animals within the first 12 hr. The prevention of cytoplasmic enzyme activity increase was limited to the first 12 hr. These studies show that morphological and biochemical alterations are more severe in old than young animals.

3690 ROLE OF URIDINE ENTRAPPED IN LIPOSOMES IN GALACTOSAMINE-INDUCED HEPATITIS. (Eng.)

Mathias, C.; Dorai, D. T.; Bachhawat, B. K. (Christian Medical Coll. Hosp., Vellore 632 004, India). *Ind. J. Biochem.* 14(2):142-146; 1977.

The therapeutic value of using the liposomes to deliver substances to liver cells was studied in galactosamine-induced hepatitis. A single i.p. injection of D-galactosamine to female rats produced morphological changes in the liver that closely resembled those observed in human viral hepatitis. The damage was dose-dependent. The dose of D-galactosamine required to produce minimal liver glycogen levels (1.5 ± 0.9 mg/g) was 75 mg/kg. The i.v. administration of free uridine (0.04 mg/g) 30 min after the injection of D-galactosamine (75 mg/kg) slightly decreased the glycogen depletion, resulting in values of 6.4 ± 1.1 mg/g of liver tissue. The same dose of uridine entrapped in three different types of liposomes was then administered to rats treated with the standard dose of D-galactosamine. Animals treated with liposomes containing either stearylamine or dicetylphosphate failed to produce a protective effect on the liver glycogen levels (0.8 ± 0.2 mg/g and 5.1 ± 1 mg/g, resp.) and liver morphology. In contrast, animals receiving phosphatidic acid-containing liposomes showed a marked regeneration of liver glycogen (25 ± 9 mg/g). The liver morphology was restored to near normal in the animals treated with phosphatidic acid-containing liposomes. The liposomes may be of value for transporting substances to the hepatocytes in the treatment of viral hepatitis.

3691 MALIGNANT TUMORS IN RATS FED NAFENOPIN, A HEPATIC PEROXISOME PROLIFERATOR. (Eng.)

Reddy, J. K.; Rao, M. S. (Northwestern Univ. Medical Sch., Chicago, IL 60611). *J. Natl. Cancer Inst.* 59(6):1645-1650; 1977.

The carcinogenicity of the hypolipemic hepatic peroxisome proliferator, nafenopin (2-methyl-2-[*P*-(1,2,3,4-tetrahydro-1-naphthyl)phenoxy]propionic acid; Su-13,437) was tested in 15 male F344 rats. The animals received nafenopin at a dietary concentration of 0.1% until the end of the experiment at 25 months. Between 18 and 25 months, 12 of 15 rats developed tumors. Eleven of the 15 rats developed hepatocellular carcinomas, and 3/15 developed pancreatic acinar cell tumors, including 1 metastasizing carcinoma. The hepatocellular carcinomas as well as the acinar cell carcinoma of the pancreas were successfully transplantable through six generations. These studies confirm the carcinogenicity of nafenopin in F344 rats.

3692 HEPATOTOXICITY OF SALICYLATES IN MONOLAYER CELL CULTURES. (Eng.)

Tolman, K. G.; Peterson, P.; Gray, P.; Hammar, S. P. (Univ. Utah Coll. Medicine, 50 N. Medical Drive, Salt Lake City, UT 84132). *Gastroenterology* 74(2, Part 1):205-208; 1978.

The influence of graded doses of sodium salicylate (10, 20, 30, 40, and 50 mg/dl) on rat liver cells cultured in monolayers was assessed by measuring lactic dehydrogenase activity in culture media after cell incubation. Morphological alterations were studied by electron microscopy. The influence of different albumin concentrations in the media on toxicity was also evaluated. Lactic dehydrogenase concentrations rose with increasing doses of salicylate up to 40 mg/dl. High albumin concentrations were associated with reduced salicylate toxicity. These findings suggest that salicylate-induced hepatic injury is dose related and may be influenced by serum albumin levels.

3693 EFFECT OF ACUTE UREMIA ON ARGININE METABOLISM AND UREA AND GUANIDINO ACID PRODUCTION BY PERFUSED RAT LIVER. (Eng.)

Perez, G. O.; Rietberg, B.; Owens, B.; Schiff, E. R. (Miami Veterans Admin. Hosp., 1201 N.W. 16th St., Miami, FL 33125). *Pfluegers Arch.* 372(2):275-278; 1977.

The effect of an acute loss of renal function on the hepatic metabolism of arginine and other urea cycle intermediates was investigated. Since arginine is a precursor of urea and other guanidino derivatives, its metabolism was studied in acute uremia using the isolated perfused rat liver. Female Sprague-Dawley rats underwent bilateral nephrectomy or sham operation 48 hr prior to liver perfusion. [Gaunidino ^{14}C]arginine (50 μCi) and unlabeled arginine and aspartic acid were added to the recycling perfusate 15 min prior to liver perfusion. Perfusate concentrations of urea and other guanidino derivatives were measured with high-pressure liquid chromatography. After the initial 30 min of perfusion, net uptake of arginine was lower, and net release of guanidino-succinic acid (GSA) was higher in the livers of acutely uremic rats. Net release of urea was also higher in uremia but the results did not achieve statistical significance. In uremia, the percentage conversion of ^{14}C arginine to ^{14}C urea was significantly ($p < 0.05$) higher (79 ± 5%) than in controls (58 ± 7%). These results demonstrate increased GSA production by livers of acutely uremic rats and suggest that acute uremia may be associated with increased arginine utilization and increased production of urea.

3694 ALTERATIONS OF RAT LIVER SUBSEQUENT TO HEAT OVERLOAD. (Eng.) Bowers, W. D., Jr.; Hubbard, R. W.; Leav, I.; Daum, R.; Conlon, M.; Hamlet, M. P.; *et al.* (US Army Res. Inst. Environmental Medicine, Natick, MA 01760). *Arch. Pathol. Lab. Med.* 102(3):154-157; 1978.

Specimens were taken from the liver in male Sprague-Dawley rats during a study to assess the rat as a model for human heat stroke. Tissues from four groups of rats were processed for light and electron microscopy. The groups consisted of control rats, rats run to exhaustion at 5 C, rats exhausted at 26 C, and rats restrained at 41.5 C until their rectal temperatures reached 42.3 C. Exhaustive exercise at 5 C produced neither fatalities nor pathological changes in the livers. Exhaustive exercise at 26 C and restraint at 41.5 C were fatal for most rats. Histological and/or ultrastructural changes, which included centrilobular necrosis, vacuolization and diminution of hepatocellular microvilli, and loss of sinusoidal endothelium, were observed in livers from rats that were run to exhaustion at 26 C and from those rats restrained at 41.5 C. This work supports the validity of the rat model, since human heat stroke results in similar hepatic changes.

3695 CONTROL OF ASCITES ABSORPTION IN ANESTHETIZED CATS: EFFECTS IN INTRAPERITONEAL PRESSURE, PROTEIN, AND FUROSEMIDE DIURESIS. (Eng.) Zink, J.; Greenway, C. V. (Faculty Medicine, Univ. Manitoba, 770 Bannatyne Ave., Winnipeg, Manitoba R3E OW3, Canada). *Gastroenterology* 73(5):1119-1124; 1977.

A plethysmographic technique was utilized to record the rate of absorption of fluid from the peritoneal cavity of anesthetized cats. In 33 cats, the rate of fluid absorption from the peritoneal cavity was directly proportional to the intraperitoneal pressure regardless of whether the intraperitoneal fluid was free from protein or contained a protein concentration equivalent to that of plasma. Fluid was absorbed with a protein concentration equivalent to that present in the peritoneal cavity. Thus, the intraperitoneal pressure is apparently an important factor controlling the accumulation of ascitic fluid, but the protein concentration of the intraperitoneal fluid does not affect the rate of reabsorption. In addition, marked diuresis induced by i.v. furosemide (3.1 mg/kg) did not appear to mobilize ascites by an effect on the reabsorption process.

3696 IMMUNOFLUORESCENCE MICROSCOPY IN EXPERIMENTALLY INDUCED, TYPE B HEPATITIS IN THE CHIMPANZEE. (Eng.) Hoofnagle, J. H.; Michalak, T.; Nowoslawski, A.; Gerety, R. J.; Barker, L. F. (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Gastroenterology* 74(2, Part 1):182-187; 1978.

Sequential liver biopsies from five chimpanzees with experimentally-induced, acute type B hepatitis were studied for immunofluorescence (IF) reactivity. In general, IF for hepatitis B surface antigen (HBsAg) and hepatitis B core antigen (HBcAg) appeared early in the course of the infection, shortly after the first appearance of HBsAg in the serum, and well before the onset of elevated transaminase values and light microscopy histopathological changes on liver biopsies. IF reactivity usually disappeared at the time of peak transaminase elevations and liver cell morphological changes, but before the disappearance of serum HBsAg. The pattern of IF reactivity, whether predominantly HBsAg or HBcAg or both, remained constant over the course of the infection for any one chimpanzee and did not appear to be correlated with clinical severity or the presence or absence of the hepatitis B virus-related e antigen. The occurrence of peak liver enzyme elevation and clinical disease at the time of disappearance or diminution of hepatic HBsAg and HBcAg expression, and not at the time of peak in IF reactivity, is consistent with the concept that tissue injury in type B hepatitis is not the result of a direct cytopathic effect of the virus, but is rather the result of an indirect, host-mediated effect involved in the immune clearance of these viral antigens.

3697 INHIBITORY EFFECTS OF JAUNDICE ON REGENERATING LIVER. (Eng.) Yamamoto, M.; Yamada, T.; Ida, T.; Ozawa, K. (Kyoto Univ., Faculty Medicine, 54-Kawaramachi, Shogoin, Sakyo-ku, Kyoto 606, Japan). *Res. Exp. Med. (Berl.)* 171(2):121-128; 1977.

The effects of partial hepatectomy on energy charge (ATP+1/2ADP/ATP+ADP+AMP) and mitochondrial oxidative phosphorylation were studied in normal and jaundiced Wistar rats. In normal rats the energy charge levels of the remnant liver decreased only slightly with a rise in the phosphorylative activity of the mitochondria at an early stage after hepatectomy, and then rapidly returned to normal. In rats in which jaundice was induced by common bile duct ligation, the energy charge levels of the liver decreased to approximately 0.800 from a normal value of about 0.849, although their mitochondrial oxidative phosphorylation was within normal limits. In jaundiced rats, the energy charge levels of the remnant liver after partial hepatectomy decreased markedly without a return toward normal. The mitochondrial phosphorylative activity increased to only about 50% of hepatectomized normal rats after partial hepatectomy. More than 70% of jaundiced rats died within 24 hr after partial hepatectomy. It is suggested that jaundice inhibits the enhancement of mitochondrial ATP generation that is usually seen in regenerating liver and that is necessary to provide sufficient energy for the energy-requiring biosynthetic process as in the early process of liver regeneration.

3698 EFFECT OF CHRONIC RENAL FAILURE IN RATS ON STRUCTURE AND FUNCTION OF THE HEPATIC ENDOPLASMIC RETICULUM. (Eng.) Black, M.; Biempica, L.; Goldfischer, S.; Grossman, S.; Arias, I. M. (Temple Univ. Sch. Medicine, 3420 N. Broad St., Philadelphia, PA 19140). *Exp. Mol. Pathol.* 27(3): 377-391; 1977.

To determine whether features associated with the uremic syndrome in liver disease could be related to changes in the function of the hepatic endoplasmic reticulum, functional, histochemical, and ultrastructural studies of the liver were performed in rats rendered chronically azotemic following unilateral nephrectomy and segmental infarction of the remaining kidney. Zoxazolamine paralysis time (6.6 ± 0.3 hr) and ketamine narcosis time (50.0 ± 3.0 min) in rats with renal failure were prolonged in comparison with sham operated controls (4.2 ± 0.2 hr and 40.2 ± 4.3 min, resp.; $p<0.01$ and $p>0.01$, resp.). Cytochrome P-450 content and benzphetamine and aminopyrine demethylase activities were decreased in the animals with renal failure, and *o*-aminophenol uridine diphosphate-glucuronyl transferase activity was unaltered. Histochemical examination of the liver by light microscopy revealed little abnormality except for lipid accumulation associated with increased serum cholesterol and triglyceride concentrations. Electron microscopy demonstrated alterations in endoplasmic reticulum and lysosomes. Dichloroethane treatment of uremic rats prevented the ultrastructural changes and enhanced drug metabolizing enzyme systems. These observations indicate that experimental chronic renal failure influences the structure and function of the hepatic endoplasmic reticulum and support the hypothesis that some features of the uremic syndrome in man may result from altered hepatic subcellular function.

3699 STUDIES ON THE EFFECT OF LONG-TERM EXPOSURE TO NITROGEN DIOXIDE ON SERUM AND LIVER PROTEINS LEVEL AND ENZYME ACTIVITY IN GUINEA PIGS. (Eng.) Drozdz, M.; Kucharz, E.; Ludyga, K.; Molska-Drozdz, T. (Silesian Medical Sch., Sosnowiec, Poland). *Eur. J. Toxicol.* 9(5):287-293; 1976.

SECRETION AND METABOLISM

Intestine

3759 TANNIC ACID AND OXIDIZED TANNIC ACID ON THE FUNCTIONAL STATE OF RAT INTESTINAL EPITHELIUM. (Eng.) Mitjavila, S.; Lacombe, C.; Carrera, G.; Derache, R. (INSERM- U.87, Institut de Physiologie, 2 Rue Francois Magendie 31400, Toulouse, France). *J. Nutr.* 107(12):2113-2121; 1977.

To ascertain the origin of fecal nitrogen and the effect of tannic acid on the intestinal mucosa, diets containing tannic acid (3% of dry matter) were fed to male Wistar rats for 33 days. To explain the effect of oxidation of tannins, diets containing oxidized tannic acid or tannic acid associated with an antioxidant (sodium sulfite) at the level of 1% of dry matter were also administered. The increased excretion of sialic acid (from

2.209 ± 0.0583 to 3.03 ± 0.140 g, $p<0.001$) and glucosamine (from 0.215 ± 0.0147 to 0.400 ± 0.0139 g, $p<0.001$) during tannic acid ingestion indicated that the excess of fecal nitrogen mainly corresponds to the mucus hypersecretion observed by histology. Fecal analysis revealed perturbations in movements of water and ions. The study of the metabolic activity of isolated enterocytes and the activity of some enzymes in a homogenate of these cells showed an inhibition of oxygen consumption and succinic dehydrogenase activity. The addition of sodium sulfite to the diet had little effect on the action of tannic acid; however, the addition of previously oxidized tannin reduced the effects observed, particularly in the case of fecal nitrogen loss.

3760 SYNTHESIS OF MACROMOLECULES BY INTESTINAL CELLS INCUBATED WITH AMMONIA. (Eng.)

Topping, D. C.; Visek, W. J. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN 37830). *Am. J. Physiol.* 233(4):E341-E347; 1977.

Studies were conducted to determine whether concentrations of ammonia normally present in the intestinal tract of mammals and birds alter synthesis of macromolecules in isolated intestinal epithelial cells and to gain information about the possible role of ammonia in determining the RNA and DNA content of intestinal cells when animals are maintained in a conventional environment. Mucosal cells isolated from the small intestine of chicks and rats were incubated with ammonia (10 mM). NH_4Cl treatment increased glucose metabolism in cells from both species. Ammonia stimulated incorporation of precursors into RNA and decarboxylation of orotic acid by cells isolated from chickens, but an increase in incorporation of precursors into DNA was not observed in cells from either species. Cultured embryonic chicken duodena showed increased incorporation of orotate into RNA with NH_4Cl added to the medium. Rats immunized against jack bean urease showed lower urease activity per gram of dry intestinal content, lower intestinal weight, lower mucosal cell and total gut protein, and less protein per unit weight of DNA in the mucosal cell fraction. The results support the conclusion that ammonia produced in the intestine by bacterial ureases causes significant changes in the content of RNA and protein in intestinal cells.

3761 EFFECTS OF COLCHICINE TREATMENT ON RAT INTESTINAL DISACCHARIDASE ACTIVITIES.

(Ger.) Hartwich, G.; Broll, R.; Domschke, W. (Medizinische Universitatsklinik Erlangen, D-852 Erlangen, W. Germany). *Exp. Pathol. (Jena)* 13(4/5):198-208; 1977.

The effect of colchicine treatment on maltase, lactase, β-fructofuranosidase, and cellobiase activities in the jejunal mucosa was studied in male Wistar rats free of specific pathogens. Colchicine was administered i.p. in single doses of 1 or 0.5 mg/kg or in five 0.1 mg/kg-doses at 24-hr intervals. The enzyme activities were measured at 24-hr intervals from the first until the 10th or 14th day, and were related to the tissue protein content. Both regimens of colchicine caused significant ($p<0.001$-0.01) reduction of all enzyme activities, which failed to return to normal during the observation period. The first decline in the enzyme activities lasted until the 2nd or 3rd day after administration, which was followed by an increase between days 2 and 3 or 3 and 4 and then a second drop. These considerable reductions of the enzyme activity were accompanied by slight microscopic changes only. Hydropic swelling of the cryptic cells was seen after 24 hr, partly associated with granular disorganization of the cytoplasm, necrosis of single cells, depletion of mucus in the goblet cells, and edema of the villous stroma. The crypts were enlarged. Mitoses were only seldom seen. The profile of the enzyme activities demonstrated the double action of colchicine (direct toxic injury of the enzymes in the differentiated cells of the villi and reduced supply of enzymes by the crypts due to the inhibiting action on mitosis), and the findings support the hypothesis that the cells developing by enhanced proliferation during the recovery phase have a still incomplete enzyme system. This latter fact may be the cause of the delayed restoration of the enzyme activities compared to the progress in morphological restoration. The findings indicate that colchicine treatment may cause reversible maldigestion of dietary disaccharides in man.

3762 PARALLEL BETWEEN CIRCADIAN RHYTHMS OF INTESTINAL DISACCHARIDASES AND FOOD INTAKE OF RATS UNDER CONSTANT LIGHTING CONDITIONS.

(Eng.) Nishida, T.; Saito, M.; Suda, M. (Ehime Univ. Sch. Medicine, Shigenobu, Onsen-gun, Ehime 791-02, Japan). *Gastroenterology* 74(2, Part 1): 224-227; 1978.

The relationship between the circadian rhythmic changes in the disaccharidase activities of the small intestine and the circadian feeding pattern was investigated in male Wistar rats kept in the dark or in the light continuously for 4 weeks. Rats kept continuously in the light and fed *ad libitum* showed no rhythmic change in food intake or disaccharidase activities, but when they were only fed during a restricted time of day (9 AM to 3 PM), their disaccharidase activities showed rhythmic changes with higher activities around the feeding time. In contrast, rats kept continuously in the dark and fed *ad libitum* showed circadian variations in food intake and disaccharidase activities essentially similar to rats kept under the normal light-dark lighting schedule. These findings show that the rhythm of disaccharidase activities is synchronized with the feeding rhythm, not with the lighting rhythm.

3763 BRUSH BORDER PEPTIDASES AND ARYLAMIDASES IN THE EXPERIMENTAL BLIND LOOP SYNDROME OF THE RAT.

(Eng.) Mazzacca, G.; Musella, S.; Andria, G.; D'Agostino, L.; Cimino, L.; Budillon, G. (Nuovo Policlinico, Via S. Pansini, I-80131, Napoli, Italy). *Acta Hepatogastroenterol. (Stuttg.)* 24(5):364-367; 1977.

Peptidase and arylamidase activities were assessed in purified brush borders from the jejunum of Wistar rats with surgically created blind loops and in controls. The blind loop segment and the jejunum proximal and distal to the blind loop were studied. The blind loop syndrome was documented by the presence of macrocytic anemia. In rats with the blind loop syndrome, enzymatic activities that hydrolyze sucrose, L-leucyl-beta-naphthylamide, L-lysyl-beta-naphthylamide, alpha-L-glutamyl-beta-naphthylamide, L-phenylalanylalanine, and L-leucyl-glycine were significantly reduced as compared to those in controls ($p<0.001$). After a short course of antibiotic therapy (chloramphenicol, 100-150 mg/day, 7 days, p.o.), enzymatic activities returned to normal. These findings suggest that intestinal mucosal damage in rats with the blind loop syndrome is reversible.

3764 INDUCTION OF Na-K-ATPase IN PLASMA MEMBRANES OF RAT CECUM MUCOSA BY DIET: TIME COURSE AND KINETICS. (Eng.) Schiffl, H.; Loeschke, K. (Medizinische Klinik Innenstadt der Universitat Munchen, Ziemssenstrasse 1, D-8000 Munchen 2, W. Germany). *Pfluegers Arch.* 372(1):83-90; 1977.

Using cecum mucosa homogenates and cellular subfractions of male SPF Wistar rats, obtained by differential centrifugation, the process by which dietary polyethylene glycol (PEG) induces cecal Na$^+$-K$^+$-activated adenosine triphosphatase (Na-K-ATPase) activity was studied with respect to time course, subcellular distribution, and properties of the enzyme. In comparison with controls, Na-K-ATPase specific activity was stimulated in PEG-treated (160 g/1 in drinking water) rats in the total homogenate and in the microsomal (105,000 x *g*) sediment but not in the mitochondrial (9,000 x *g*) or nuclear (1,000 x *g*) sediment. The specific activity of Mg-ATPase did not change in any of the fractions. Na-K-ATPase induction was statistically significant after 2 days and complete after 1-2 weeks, in parallel with the previously described stimulation in net sodium absorption. Kinetic analysis showed V_{max} for ATP to be doubled while K_m for ATP, Na, and K as well as the optimal Mg/ATP ratio and K_i for ouabain remained unchanged. It is proposed that Na-K-ATPase and active sodium transport are closely associated in rat cecum and that dietary Na-K-ATPase stimulation is due to the induction of more enzyme molecules per unit basolateral cell membrane.

3765 ESTIMATION OF CHOLECYSTOKININ-PANCREOZYMIN (CCK) IN HUMAN PLASMA AND TISSUE BY A SPECIFIC RADIOIMMUNOASSAY AND THE IMMUNOHISTOCHEMICAL IDENTIFICATION OF PANCREOZYMIN-PRODUCING CELLS IN THE DUODENUM OF HUMANS. (Eng.) Schlegel, W.; Raptis, S.; Grube, D.; Pfeiffer, E. F. (Dept. Internal Medicine, Univ. Ulm, Ulm, W. Germany). *Clin. Chim. Acta* 80(2):305-316; 1977.

A reliable, sensitive, reproducible, and specific radioimmunoassay for cholecystokinin-pancreozymin (CCK), using rabbit antisera to highly purified porcine hormone, is described, and the assay was tested in humans. The naturally occurring variant of CCK (39-CCK, in which the ordinary CCK is lengthened from its *N*-terminus by a hexapeptide), labeled with ^{125}I and repurified by column chromatography on Sephadex G-10 and on SP-Sephadex C-25, was used as tracer. Separation of CCK from antibody-bound labeled 39-CCK was carried out using a double-antibody procedure. Nonspecific interference with the assay system was abolished by ethanol extractions. Highly purified porcine CCK was used as standard. No significant cross-reaction was found with gastrin, motilin, vasoactive polypeptide, gastric inhibitory polypeptide, natural and synthetic secretin, pancreatic glucagon, or insulin. The sensitivity of the assay is approximately 40 pg/ml of test solution. The mean plasma immunoreactive CCK concentration in 45 fasting normal subjects was 222 pg/ml, increasing after food ingestion to 480 pg/ml. Somatostatin abolished the stimulated CCK release. Elevated CCK concentrations were found in chronic pancreatitis. Immunohistochemical identification of pancreozymin cells was carried out either in surgical samples or in biopsy material. Approximately 1,650 CCK cells per cross-section were found in the human duodenum. The CCK cells usually appeared elongated, oval, or pyramidal in shape and were observed to reach the lumen with their apical cell pole. Further studies are required to elucidate the regulation mechanisms of pancreozymin release and its biological action.

3766 STUDIES ON THE RELEASE OF EXTRA-ANTRAL GASTRIN: EVIDENCE OF VAGAL INHIBITION IN THE DOG. (Eng.) Wheeler, M. H.; Bhattacherjee, S.; Psaila, J. V.; McLeish, A. R.; Poxom, V.; Owens, C.; *et al.* (Llandough Hosp., Nr. Penarth, S. Glam, Cardiff CF6 1XX, Wales). *World J. Surg.* 1(5):639-646; 1977.

The effect of resecting the gastrin-containing tissues of the antrum on basal and postprandial levels of serum gastrin was investigated in dogs. The effects of duodenal perfusion with saline and acetylcholine, and the effect of transthoracic vagotomy on serum gastrin concentrations were also investigated. Serum gastrin concentration was measured in three dogs after a meat meal; basal levels rose significantly after 10 min. After antrectomy with a Billroth I (BI), and later a Billroth II (BII) anastomosis, the basal gastrin levels were unchanged, but the rise after meat feeding was abolished. Four antrectomized dogs with a BII anastomosis and cannulae in both the duodenum and stomach were used to examine the effect of duodenal perfusion on serum gastrin. Whether the perfusate was 150 mM NaCl, 150 mM HCl, or 0.1% acetylcholine, the mean serum gastrin levels did not differ significantly from basal levels. Transthoracic vagotomy in antrectomized dogs produced a significant rise in basal gastrin levels (from 21 ± 3 pg/ml to 48 ± 3 pg/ml, $p<0.005$), but did not restore the response to a meat meal or duodenal perfusion. Parallel studies were conducted in six antrectomized, vagotomized patients who had undergone

Roux-en-Y conversion for postgastrectomy bilious vomiting, and in two patients after total gastrectomy. Duodenal perfusion via duodenostomy tubes with 150 mM NaCl, 150 mM HCl, fat emulsion, and an amino acid mixture did not raise serum gastrin above basal levels. Since meat feeding and duodenal perfusion in antrectomized dogs and humans failed to stimulate a rise in serum gastrin, the intestinal phase of gastric secretion is probably mediated by gastrin. The results following vagotomy in the dog suggest that extragastric basal gastrin release is vagally inhibited or that vagotomy interferes with the catabolic destruction of gastrin.

3767 CHANGES IN THE STRUCTURAL LOCALIZATION OF GLYCOGEN DURING GLUCOSE RESORPTION. (Ger.)

Varkonyi, T.; Wittmann, T.; Karacsony, G.; Varro, V. (I. Medizinische Universitatsklinik, H-6701 Szeged, Hungary). *Z. Gastroenterol.* 15(9):565-571; 1977.

To investigate quantitative changes in the glycogen granula contents of the small intestinal mucosa, the localization of glycogen in the jejunal wall was studied during glucose resorption in 10 fasting dogs with isolated jejunal loops using light microscopy with Best-carmine staining. Isotonic glucose solution was introduced into the jejunal lumen. Glycogen was detected in the form of red granules in a patchy arrangement in the supranuclear cytoplasmic region of the enterocytes during the initial phase of the glucose resorption. About 15 min after the beginning of resorption, glycogen also appeared in steadily increasing quantities in the lamina propria. The injection of glucagon (50-100 μg/15 min) into the artery of the intestinal loop during glucose resorption caused the total disappearance of glycogen from the enterocytes, but the glycogen load of the lamina propria cells remained unchanged. The findings indicate that the epithelial cells of the small intestine are the primary target of glucagon.

3768 THE DIGESTION AND TRANSMISSION OF LABELLED IMMUNOGLOBULIN G BY ENTEROCYTES OF THE PROXIMAL AND DISTAL REGIONS OF THE SMALL INTESTINE OF YOUNG RATS. (Eng.)

Morris, B.; Morris, R. (Dept. Zoology, Univ. Nottingham, University Park, Nottingham NG7 2RD, England). *J. Physiol. (Lond.)* 273(2):427-442; 1977.

The breakdown products produced by the digestive activities of the proximal and distal regions of the small intestine of suckling Wistar rats were investigated to provide information on the functional differences between proximal and distal enterocytes. Density gradient centrifugation of samples prepared from proximal gut homogenates after intralumenal injection of ^{125}I-labeled IgG was used to prepare batches of IgG fragments according to sedimentation coefficients. The radioactivity in the vascular compartments, viscera, and carcasses of rats aged 14-15 days, was partitioned using ultrafiltration 2 hr after the injection of labeled IgG into the proximal and distal regions of the small intestine. Radioactive samples prepared by these methods were reintroduced into young rats by intracardiac injection, and the rate at which they were removed from the vascular compartment was assessed. Proximal enterocytes transmitted about 39% of the IgG that had been removed from the intestine in intact form. Most of this was retained in the vascular compartment; they degraded up to about 57% of the total removed into fragments less than 1,000 in molecular weight and about 4% into intermediate-sized fragments. Distal enterocytes degraded almost 90% of the IgG processed into fragments less than 1,000 in molecular weight, and about 8% into fragments greater than 100,000 in molecular weight. Fragments of all sizes were cleared rapidly from the circulation into the viscera and carcass. The results show that, even in the absence of peptic digestion, the proximal and distal enterocytes contain efficient mechanisms for digesting protein.

3769 IMMUNOCYTOCHEMICAL AND HISTOCHEMICAL STUDIES ON INTESTINAL EPITHELIAL CELLS PRODUCING BOTH LYSOZYME AND MUCOSUBSTANCE. (Eng.)

Montero, C.; Erlandsen, L. (Dept. Anatomy, Univ. Minnesota, Minneapolis, MN 55455). *Anat. Rec.* 190 (1):127-142; 1978.

The existence of lysozyme mucus-producing cells was investigated in both the rat and human intestine. The simultaneous demonstration of lysozyme (using the unlabeled antibody enzyme method) and mucosubstances (by staining with the PAS and Alcian Blue pH 2.5 techniques) led to the identification of a new subpopulation of mucus-producing cells containing lysozyme in small intestinal specimens from normal rats and from patients with inflammatory bowel diseases. These cells, containing both mucosubstances and lysozyme, were located in the lateral walls of the crypts of Lieberkuhn, but were occasionally found also in or near the tips of the villi. The specific staining for lysozyme was observed in the apical and/or basal cytoplasm of these mucus-producing cells and was readily detected in sections counterstained for mucosubstances with Alcian Blue. The localization of these mucus-producing cells was similar both in the normal rat and in the pathological human specimens. Absorption controls and controls where a nonimmune serum was substituted for the specific antilysozyme serum confirmed the specificity of the lysozyme localization.

3770 NUCLEIC ACID AND PROTEIN CONTENT OF RAT CECUM MUCOSA IN DIETARY ADAPTATION-GROWTH BY CELLULAR HYPERPLASIA. (Eng.)

Loeschke, K.; Resch, W. (Medizinische Klinik Innenstadt der Universitat Munchen, Ziemssenstrasse 1, D-8000 Munchen 2, W. Germany). *Pfluegers Arch.* 372(1):91-94; 1977.

DNA, RNA, and protein content of the isolated cecum mucosa was determined in control rats and rats with adaptive cecum growth induced by dietary polyethylene glycol (administered in drinking water at 160 g/l). Feeding the polymer resulted in an increase in the total amount of mucosal nucleic acids and protein that was statistically significant after 2-4 days and reached twice the control value after 2 months. During growth, the protein/DNA, protein/RNA, and RNA/DNA ratios remained unaltered, indicating hyperplasia and not hypertrophy of the epithelial cells. The water content of the mucosa increased from 75% to 81% during adaptation, possibly related to the stimulation in active sodium transport reported earlier. Recalculation of parallel Na-K-ATPase data on the basis of DNA content demonstrated a doubling of Na-K-ATPase activity per mg DNA in the fully adapted cell.

3771 SITE OF INTESTINAL DIPEPTIDE HYDROLYSIS.

(Eng.) Wiseman, G. (Physiology Dept., The Univ., Western Bank, Sheffield S10 2TN, England). *J. Physiol. (Lond.)* 273(3):731-743; 1977.

The effects of 12 dipeptides and their free amino acids on the active transport of D-glucose across the mucosa of sacs of everted hamster small intestine were studied to determine the cellular site of final hydrolysis of the dipeptides. All dipeptides had a partially inhibitory effect on the active transport of D-glucose (5.55 mM) when present at initial concentrations of 5 mM (except prolylglycine, which had an inhibitory action at a 10 mM initial concentration). Marked inhibition occurred with glycyl-L-alanine, L-alanyl-L-alanine, and L-leucyl-L-alanine, all of which reduced the final D-glucose concentration ratio to about 60% of control values. Experiments that compared the effectiveness of each dipeptide with the effectiveness of its constituent free amino acids in suppressing D-glucose active transport permitted the classification of the dipeptides into two categories. Class 1 dipeptides (L-alanyl-glycine, glycyl-glycine, L-valyl-L-valine, L-alanyl-L-valine, L-valyl-L-alanine, and L-prolylglycine) were either more effective or less effective than their component amino acids at identical concentrations. It is suggested that these dipeptides are hydrolyzed beyond the locus of the active transport mechanism for D-glucose (i.e., the brush border or outer cell surface) and they are designated deep dipeptides; their locus of hydrolysis is perhaps within the cell. In contrast, L-alanyl-L-alanine, L-leucyl-L-leucine, glycyl-L-alanine, L-alanyl-L-leucine, L-leucyl-L-alanine, and glycyl-L-proline were only as effective in suppressing D-glucose active transport as equimolar amounts of their respective amino acids. The locus of hydrolysis of these six dipeptides is suggested to be superficial to the locus of the D-glucose active transport mechanism (i.e., that both events occur near the surface). These latter dipeptides are designated as class 2, superficial dipeptides. Since all the dipeptides partially inhibited D-glucose active transport, more than one mechanism for active sugar absorption may exist; further studies are needed to investigate these questions.

3772 CHARACTERISTICS OF POTASSIUM SECRETION IN THE MAMMALIAN COLON.

(Eng.) Bastl, C.; Kliger, A. S.; Binder, H. J.; Hayslett, J. P. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Am. J. Physiol.* 234(1):F48-F53; 1978.

The characteristics of potassium transport in the colon were analyzed by determining the forces governing potassium movement, the influence of flow rate on net movement, and the response to acute and chronic changes in potassium balance in Sprague-Dawley rats. There was no evidence for active potassium transport since, under steady-state conditions, the secretion occurs down an observed electrochemical gradient that was not statistically different from the predicted value. The secretion rate rose promptly in response to acute hyperkalemia and fell to zero net movement in chronic potassium deficiency. In contrast to the renal distal tubule, potassium secretion in the colon is not flow dependent. In further experiments designed to examine overall transport characteristics in the colon, sodium was shown to be absorbed against an electrochemical gradient of approximately 60 mV, and water permeability and sodium transport in the colon was not increased by vasopressin. The rate of sodium absorption in the colon, unlike the distal tubule, is not flow dependent.

3773 ENDOGENOUS ACID RELEASES SECRETIN IN MAN.

(Eng.) Domschke, W.; Greenberg, G. R.; Domschke, S.; Bloom, S. R.; Mitznegg, P.; Sprugel, W.; *et al.* (Dept. Medicine, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 24(5):362-363; 1977.

The effect of gastric acid secretion on secretin release was investigated in six healthy volunteers. Pentagastrin (1.5 µg/kg/hr i.v.) was administered with and without aspiration of gastric contents, and plasma secretin was estimated by radioimmunoassay. Pentagastrin administration with continuous aspiration produced no change in plasma secretin immunoreactivity. Pentagastrin administration without aspiration of gastric juice resulted in a steadily increasing plasma secretin level, which was significantly elevated ($p<0.05$) at the end of 60 min of pentagastrin infusion and also in the postinfusion hour. These results are compatible with the concept that the delivery of endogenous acid from the stomach to the duodenum contributes to secretin release, which in turn may serve as a physiological stimulus for pancreatic bicarbonate secretion.

3774 VITAMIN B_{12} PRODUCTION BY THE GASTROINTESTINAL MICROFLORA OF BABOONS FED EITHER VITAMIN B_{12} DEFICIENT DIET OR A DIET SUPPLEMENTED WITH VITAMIN B_{12}.

(Eng.) Uphill, P. F.; Jacob, F.; Lall, P. (Nuffield Inst. Comparative Medicine, Regent's Park, London NW1 4RY, England). *J. Appl. Bacteriol.* 43(3):333-344; 1977.

To determine whether the intestinal flora play a part in vitamin B_{12} nutrition in the baboon, the vitamin B_{12}-producing capacity of microorganisms isolated from baboon feces and gastric contents was measured using *Lactobacillus leichmannii*. The animals were fed either a diet deficient in or supplemented with (controls) vitamin B_{12}. Samples of gastric and small intestinal contents, obtained at laparotomy from two young vitamin B_{12}-deprived baboons, contained varying quantities of vitamin B_{12}. Many of the organisms isolated from these aspirates produced vitamin B_{12} *in vitro*. The highest levels of vitamin B_{12} were produced by anaerobic organisms. Gastric juice samples from vitamin B_{12}-deprived and control baboons contained similar types of organisms with similar vitamin B_{12}-producing capacity. The vitamin B_{12} content, pH, and total bacterial counts of gastric juice samples aspirated after a 6-hr fast from vitamin B_{12}-deprived baboons were not significantly different from those of the control animals. The pH values of gastric juice samples aspirated 18 hr after feeding, however, were significantly lower ($p<0.001$) than those of 6-hr fasting samples in both groups. The B_{12} content in gastric juice aspirated 18 hr after feeding was significantly greater ($p<0.001$) only in the B_{12}-deprived animals. The mean vitamin B_{12} levels in the total volumes of gastric juice aspirated after each fasting period were similar. The results suggest that gastrointestinal flora are involved in the vitamin B_{12} status of the baboon.

3775 EXPERIMENTAL CLINDAMYCIN-ASSOCIATED COLITIS IN RABBITS: EVIDENCE FOR TOXIN-MEDIATED MUCOSAL DAMAGE. (Eng.) Katz, L.; LaMont, J. T.; Trier, J. S.; Sonnenblick, E. B.; Rothman, S. W.; Broitman, S. A.; *et al.* (Harvard Medical Sch., Boston, MA). *Gastroenterology* 74(2, Part 1): 246-252; 1978.

To study clindamycin colitis under controlled laboratory conditions, severe enterocolitis was produced in rabbits by the p.o. administration of clindamycin in doses comparable to those used in humans. Rabbits given clindamycin (15 mg/kg/day) by nasogastric tube developed diarrhea within 48 to 72 hr that was uniformly fatal by 72 to 96 hr. Controls given comparable doses of ampicillin, tetracycline, neomycin, vancomycin, or saline remained well. At autopsy, the major gross pathological finding was limited to the cecum, which was massively dilated with watery stool. The light microscopic findings in the cecum included necrosis of the surface epithelium and a prominent inflammatory infiltrate in the lamina propria. Fatal clindamycin colitis was prevented in all of 10 tested rabbits by co-administration of vancomycin (30 mg/kg/day); co-administration of penicillin or neomycin prevented the ileocolitis in 3 of 5 and 1 of 5 animals, resp. Cell proliferation, measured by radioautography after $[^3H]$thymidine injection, was significantly increased in cecal mucosa but not in the more distal colonic or small intestinal mucosa during clindamycin administration. Protein synthesis, as determined by incorporation of $[^3H]$leucine into intestinal slices, was significantly increased in both the ileum and cecum after 48 hr of clindamycin administration. Cell-free, sterile extracts of cecal contents of clindamycin-treated animals were injected into ileal loops of untreated rabbits. These fecal extracts produced a severe, hemorrhagic ileitis, although control filtrates from clindamycin-vancomycin-treated animals produced no histological changes. Using selective anaerobic culture media, there was an increase in clostridial species after 48 hr of clindamycin treatment (from 10^5 organisms/g of cecal content in controls to 10^8/g) and a reduction in clindamycin-vancomycin-treated animals (to 10^4 organisms/g). The pathogenesis of clindamycin-associated colitis in rabbits appears to be mediated by a bacterial toxin present in the cecal contents.

GENERAL

3790 THE MECHANISM OF THE CHANGES IN SPLANCHNIC BLOOD FLOW AFTER FEEDING. (Eng.) Benyo, I.; Sandor, J.; Szabo, G. (Semmelweis Univ. Medical Sch., Mezo Imre ut 17, H-1430, Budapest, Hungary). *Res. Exp. Med.* 171(3):255-261; 1977.

The mechanism of the transitory increase in splanchnic blood flow after feeding was studied in dogs. The introduction of hydrolyzed protein solution into the duodenum increased hepatic artery flow by 5.6 ± 3.3% ($p>0.05$) and portal venous flow by 13.6 ± 3.6% ($p<0.05$). Total hepatic blood flow increased 26.4 ± 3.3% ($p<0.001$). The reaction was smaller than after the introduction of 0.1 N HCl (17.9 ± 2.8% increase in hepatic artery flow and 32.3 ± 4.3%, $p<0.001$ increase in portal venous flow). Total hepatic blood flow increased 11.3 ± 2.3% ($p<0.01$-0.05). The introduction of a 30% glucose solution had no effect on splanchnic circulation. Splanchnicotomy combined with celiac ganglion denervation as well as the blockade of the sympathetic alpha receptors abolished the circulatory reaction to intraduodenal acid administration. Both interventions led, however, to a decrease in splanchnic vascular resistance similar to that observed after intraduodenal introduction of acid in normal dogs. It is concluded that the circulatory reaction occurring after the acidification of the duodenal contents after feeding is due to the reduction or abolition of the sympathetic vasomotor tone in the splanchnic vascular bed.

3791 MICROCIRCULATION STUDIES OF THE VILLUS OF THE SMALL INTESTINE OF THE RAT IN VIVO. (Ger.) Knoblauch, M.; Holliger, Ch. (Medizinische Klinik, Kantonsspital, CH-8091 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 107(40): 1391-1399; 1977.

A method of studying the microcirculation in the jejunal villus of the living rat is described. The method used is based on the trans illumination of the exposed mucosa, and it permits the measurement of the velocity of plasma gaps and of the diameter of various vessels. The motility of the gut is overcome by allowing the intestine to adhere to the water immersion lens. The animals were fed *N*-acetyl-L-cysteine to prevent mucus production. A direct arteriovenous connection between the arterioles and the venous system of the villus is postulated. The plasma gap velocity was 1.78 ± 0.62 mm/sec in the arterioles and 0.42 ± 0.08 mm/sec in the capillaries. The measured diameter of the erythrocyte column in the vessels was 9.14 ± 1.89 μm in the central artery, 5.88 ± 1.05 μm in the proximal third of the arcade arteriole, 6.69 ± 1.04 µm in the middle third, 8.86 ± 1.63 µm in the distal third of the arcade arteriole, 4.56 ± 0.57 µm in the capillaries, and 13.58 ± 2.67 µm in the venules. The method also allows the puncture of villus vessels.

3792 EFFECT OF HYPEROSMOLALITY ON VASCULAR RESISTANCE AND LYMPH FLOW IN THE CAT ILEUM.

(Eng.) Levine, S. E.; Granger, D. N.; Brace, R. A.; Taylor, A. E. (Univ. Mississippi Medical Center, Jackson, MS 39216). *Am. J. Physiol.* 234(1):H14-H20; 1978.

To determine the effects of locally infused hyperosmotic solutions of glucose, urea, and sodium chloride on intestinal hemodynamics and tissue hydration, systemic arterial pressure, superior mesenteric arterial and venous pressures, blood flow, lymph flow, and intestinal volume were monitored continuously from an autoperfused loop of cat ileum. The solutes were infused into the superior mesenteric artery at varying rates (0.20-0.80 ml/min) and concentrations (300-1,500 mOsm/kg). Infusion of iso-osmotic solutions of either NaCl or glucose did not significantly alter vascular resistance, tissue volume, or lymph flow. A consistent effect of iso- or hyperosmotic urea infusions was not demonstrated. Hyperosmotic glucose and NaCl infusions both caused marked reductions in vascular resistance; however, the magnitude and time course of the response differed between solutes. Glucose was shown to produce a 2.70% decrease in vascular resistance per 1% increase in plasma osmolality. The resistance responses to hyperosmotic glucose were maintained throughout the infusion period. NaCl infusions produced a 4.87% decrease in vascular resistance for each 1% increase in plasma osmolality. In addition, the NaCl infusions produced a fall in resistance, which waned with time. The osmolality increase induced by the infusion of either solute caused significant reductions in both tissue volume and lymph flow; however, the magnitude of the changes in lymph flow were not correlated to the change in either plasma osmolality or tissue volume. The results suggest that the ileal vasculature may respond more vigorously to osmolality changes than do other regional circulations.

3793 COLONIC RESPONSE TO DIETARY FIBRE FROM CARROT, CABBAGE, APPLE, BRAN, AND GUAR GUM.

(Eng.) Cummings, J. H.; Branch, W.; Jenkins, D. J. A.; Southgate, D. A. T.; Houston, H.; James, W. P. T. (Dunn Nutrition Unit, Milton Rd., Cambridge, England). *Lancet* 1(8054):5-8; 1978.

The effects of dietary fiber from different food sources were investigated in 19 healthy men. Approximately 20 g/day of concentrated dietary fiber from either carrot, cabbage, apple, bran, or guar gum was added to the controlled basal diet for 3 weeks. The subjects received no fiber during a second 3-week period. Six subjects took fiber from more than one source. Fecal weight increased by 127% on bran, 69% on cabbage, 59% on carrot, 40% on apple, and 20% on guar gum. These changes in fecal weight were correlated with an increased intake of pentose-containing polysaccharides from the fiber. On the basal diet, there were pronounced individual differences in fecal weight, and from these the response of subjects to the fiber preparations could be predicted. Addition of fiber shortened mean transit time through the gut and significantly diluted an inert marker in the feces. Diet-induced changes in colonic function may explain international differences in the prevalence of colonic disease, while personal variation in the response to dietary fiber may determine individual susceptibility to large bowel disease within a community.

3794 ENDOTOXEMIA AND LARGE INTESTINAL BLOOD FLOW IN SUBHUMAN PRIMATES.

(Eng.) Swan, K. G.; Trout, H. H., III; Reynolds, D. G. (New Jersey Medical Sch., 100 Bergen St., Newark, NJ 07103). *Circ. Shock* 4(4):369-377; 1977.

The hemodynamic effects of *Escherichia coli* endotoxin (LD_{80}) were measured in the large intestine of anesthetized Rhesus monkeys to determine whether this organ contributes to the pathogenesis of experimental shock. Inferior mesenteric arterial blood flow (IMF) was measured with an electromagnetic flow meter. Colonic blood flow distribution was measured with radioactive microspheres: Ce, Sr, and Cr were injected into the left heart. Reference blood samples were obtained from a femoral artery. The mean control IMF was 22.9 ± 2.2 ml/min. The aortic pressure was 113 ± 11 mm Hg, and portal venous pressure was 6 ± 1 mm Hg. Arterial blood pH was 7.43 ± 0.02; pO_2 and pCO_2 were 93.4 and 37.1 mm Hg, resp. All parameters were measured at hourly intervals for 4 hr. Neither IMF nor its distribution within the colon changed during the entire observation period. Aortic pressure fell to a low of 60 ± 6 mm Hg ($p<0.02$) at 3 hr; portal venous pressure, pO_2 and pCO_2 were unchanged by endotoxin. Arterial blood pH fell to 7.315 ± 0.020 at 4 hr ($p<0.01$). These observations indicate that the colon is not a "target organ" of endotoxic shock in subhuman primates, despite considerable hypotension and metabolic disturbances subsequent to near lethal endotoxemia.

DIAGNOSTIC PROCEDURES

3840 A CELLULOSE ACETATE MEMBRANE PRECIPITIN (CAP) TEST FOR AMOEBIASIS. (Eng.) Stamm, W. P.; Phillips, E. A. (17 Ennismore Gardens, London SW7 1AA, England). *Trans. R. Soc. Trop. Med. Hyg.* 71(6):490-492; 1977.

A simple precipitin test (CAP) using cellulose acetate membrane was devised and compared with the gel diffusion precipitin (GDP) test in 251 sera tested by both methods. The CAP was never negative when the GDP was positive (110 sera). Thirty-four were negative by the GDP but positive by the CAP; in all of these, the patients either had active amebiasis or had a past history of amebiasis. The CAP is technically very simple, and the result is available within 4.5 hr. In addition, the membranes can be impregnated with antigen and stored for several months. The CAP is slightly more sensitive than the GDP and remains positive longer after the patient has been cured; it appears to be equally specific.

3841 CLINICAL EVALUATION OF THE (^{14}C)CHOLYLGLYCINE BREATH TEST. (Eng.) Thaysen, E. H.; Pedersen, L. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (Baltimore, MD: University Park Press): 263-269; 1977.

The [^{14}C]cholylglycine breath test was compared with the assay combining breath and stool ^{14}C measurements to assess its value in clinical gastroenterology as a measure of increased bile acid deconjugation resulting from either small gut bacterial overgrowth or bile acid malabsorption (excess bile acid loss into the colon). Intestinal bacterial bile acid deconjugation releases glycine whose labeled carboxyl atom is then oxidized to $^{14}CO_2$ and exhaled. Fecal ^{14}C determinations are made after complete combustion of the sample. While the breath test alone cannot discriminate between the small bowel syndrome and the syndrome of bile acid malabsorption, a positive breath test with a negative stool test suggests the former, whereas a positive stool test suggests the latter (the outcome of the breath test being unimportant). Of the 19 patients without gastrointestinal disease and 55 patients with functional diarrhea, only one control had a false-positive breath test and two had positive stool test. Of 68 patients with nonbile acid-related diarrhea, 8 had positive breath tests, and 6 had positive stool tests. Seven of the eight had disorders that could be accompanied by small gut bacterial overgrowth; three of the six also presented circumstantial evidence of involvement of terminal ileum. A positive breath test with a negative stool test was registered in 55 of 86 patients with contaminated small bowel syndrome. Positive stool tests were found in 15 of 16 patients with terminal ileal resections of at least 15 cm and in 31 of 34 patients with terminal ileitis; the breath tests were positive in 8/16 and 14/34, resp. The (^{14}C) cholylglycine breath test is inferior to the complete (^{14}C) cholylglycine assay. The complete (^{14}C)-cholylglycine assay, combining breath and stool ^{14}C measurements, is sensitive and specific, and provides satisfactory discrimination between the contaminated small bowel and bile acid malabsorption syndromes. The assay is superior to any other examination known in detecting terminal ileopathy.

3842 EVALUATION OF THE INDIRECT IMMUNOFLUORESCENCE AND COMPLEMENT FIXATION TESTS FOR THE SERODIAGNOSIS OF SCHISTOSOMIASIS. (Eng.) Wilson, M.; Fried, J.; McQuay, R. M.; Sulzer, A. J. (Center for Disease Control, Atlanta, GA 30333). *Am. J. Trop. Med. Hyg.* 26(6, Part 1):1159-1163; 1977.

Sera from 24 patients with *Schistosoma mansoni* infections, 24 with *S. hematobium*, 24 with *Ascaris* and other intestinal parasites, 22 with *Trichinella spiralis*, 24 with schistosome dermatitis, and 24 healthy subjects were used to compare the sensitivity and specificity of the complement fixation (CF) and the indirect immunofluorescence (IIF) tests for schistosomiasis. Adult antigens were used in both tests. The sensitivities of the IIF and CF tests were 95% and 69%, resp.; the specificities were 98% and 100%, resp. There was no statistical difference between the number of positive reactors among those individuals with no detectable helminth infection and those infected with helminths other than schistosomes. Infected people native to endemic areas had lower reactivity in both tests than did infected U.S. citizens who resided in endemic areas for only a few years. It is concluded that the IIF test with adult antigen is more sensitive than and as specific as the CF test; therefore, the IIF test is the procedure of choice for routine diagnostic serology of schistosomiasis.

3843 USE OF TOLONIUM CHLORIDE IN THE DIAGNOSIS OF MALIGNANT GASTRIC ULCERS. (Eng.) Giler S.; Kadish, U.; Urca, I. (Beilinson Medical Center, Petah Tikva, Israel). *Arch. Surg.* 113(2):136-139; 1978.

Peroral staining with tolonium chloride (toluidine blue) was carried out in 45 patients with suspected gastric ulcer disease in an evaluation of this method for the diagnosis of malignant gastric ulcers. During endoscopy, 19 of 21 malignant ulcers and 1 of 15 benign ulcers were stained. Following surgery, 18 of 21 malignant ulcers found in the surgical specimens were stained. Eleven patients with benign ulcers underwent surgery, and none of these ulcers were found to be stained in the surgical specimens. Normal gastric mucosa and areas of gastritis appeared unchanged. Tolonium chloride staining prior to endoscopy or surgery seems to be helpful in differentiating between minute benign and malignant gastric ulcers.

3844 INHIBITION BY CONCANAVALIN A AS THE BASIS FOR A SPECIFIC ASSAY OF SERUM 5'-NUCLEOTIDASE ACTIVITY. (Eng.) Zygowicz, E. R.; Sunderman, F. W., Jr.; Horak, E.; Dooley, J. F. (Univ.

Connecticut Sch. Medicine, Farmington, CT 06032). *Clin. Chem.* 23(12):2311-2323; 1977.

A new method for assaying serum 5'-nucleotidase activity, which is based on the ability of concanavalin A to inhibit the activity of this enzyme without causing significant inhibition of alkaline phosphatase activity, is described. The method depends upon the difference between the enzymic hydrolysis of adenosine-5'-monophosphate in the presence and absence of concanavalin A. Adenosine released by the 5'-nucleotidase reaction is deaminated by a coupled reaction with adenosine deaminase to liberate inosine and ammonia; the ammonia release was measured colorimetrically. In sera from 40 healthy subjects, 5'-nucleotidase activity averaged 6.4 U/l (± 2.0; range, 3-12). In sera from 100 patients, measurements of 5'-nucleotidase activity by the new assay averaged 8% lower than by a generally accepted method in which phenyl phosphate is used to suppress hydrolysis of adenosine-5'-monophosphate by alkaline phosphatase activity. The clinical validity of the new assay was tested by measuring serum 5'-nucleotidase activities in rats with bile duct ligation and in rats treated with thioacetamide to induce hepatocellular injury. Rats with liver injury had 5'-nucleotidase activities 1.4- to 1.5-fold greater than the nucleotidase activities in controls, and this activity increased to a greater extent in rats with acute biliary obstruction than in rats with acute toxic injury of hepatic parenchymal cells; these findings are consistent with the reports of previous workers who have used other assay methods. The advantages of the new method include: excellent sensitivity and precision; freedom from interference by bilirubin, lipemia, ammonia, and hemoglobin; and low susceptibility to interference by erythrocyte 5'-nucleotidase activity. The method has two disadvantages: it is relatively time-consuming and it is not readily adaptable to automation.

3845 CONTRIBUTION OF ARTERIOGRAPHY TO THE DIAGNOSIS OF LIVER ABSCESS: OBSERVATION OF 20 CASES. (Fre.) Mandoul, M.; Joffre, F.; Carcy, J. B.; Vidal, J. L. (Service Central de Radiologie, CHU Toulouse-Purpan, 31052 Toulouse Cedex, France). *Rev. Med. Toulouse* 12(8):696-709; 1976.

Selective hepatic arteriography was performed in 20 patients with liver abscess by selective catheterization of the celiac trunk and superior mesenteric artery. Inhomogeneous, irregular arteries were found in all 20 cases, "slurred" arteries in 5, avascular tumor syndrome in all 14 cases of presuppurative hepatitis (non-collected abscess), hypervascularization in 14 cases (mostly non-collected abscesses), and micronodular opacification in 8. Hepatic arteriography was especially valuable in the diagnosis of presuppurative hepatitis.

3846 RADIONUCLIDE LIVER SPOTS: INDICATOR OF LIVER DISEASE OR A BLOOD FLOW PHENOMENON. (Eng.) Tetalman, M. A.; Kusumi, R.; Gaughran, G.; Baba, N. (Ohio State Univ. Hosp., 410 West 10th Ave., Columbus, OH 43210). *Am. J. Roentgenol.* 130 (2):291-296; 1978.

The etiology of "hot spots" in liver scans is examined by a review of four cases of superior vena caval obstruction in which there was a spectrum of liver scan findings including correlative venous collateral pathways through the portal system of the liver. It is shown that a finding of "warm spot" or of no spot is also possible. The patient who demonstrated liver hot spot was shown to have incomplete superior vena caval obstruction with numerous collateral channels below the diaphragm. A patient who initially had a hot spot of numerous collateral channels below the diaphragm at the junction between the right and left liver lobes subsequently showed a warm spot superiorly at that point; it was considerably smaller and less active than the hot spot had been. One patient with complete occlusion of the superior vena cava and one with superior vena caval obstruction secondary to carcinoma showed no spot on liver scan. It is suggested that the hot spot is a well-localized abnormal blood flow phenomenon of collateral channels unrelated to any intrinsic liver disease in which the abnormal blood flow presents the surrounding reticuloendothelial cells with a greater portion of colloid to be phagocytized than in the remainder of the liver. Warm spot may be caused by any large area of venous stasis and is probably related to the venous collateral channels in an area of localized adenomata or interstitial fibrosis. Warm spot cannot differentiate between benign and malignant disease but may suggest intrinsic liver pathology.

3847 PERCUTANEOUS TRANSVENOUS APPROACH TO LIVER BIOPSY. (Ger.) Huchzermeyer, H.; Luska, G. (Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany). *Innere Med.* 3(3):174-178; 1976.

A new method of liver biopsy, percutaneous transvenous liver biopsy, affording high accuracy is described. The right internal jugular vein, the subclavian vein, or the left internal jugular vein can be used for the biopsy. The biopsy sample is taken by a Ross needle, and the procedure requires local anesthesia. This technique was used in 22 patients with an obstruction syndrome; no major complications were seen. Transvenous liver biopsy is indicated for patients with blood clotting disorders, long-standing obstructive jaundice, or biliary peritonitis, i.e., for patients in whom transperitoneal liver biopsy is contraindicated. Consequently, transvenous biopsy is not an alternative to transperitoneal blind biopsy. Transvenous liver biopsy is contraindicated in purulent cholangitis, liver abscess, cystic liver, echinococcosis, and cardiac arrhythmia. It can be combined with transjugular cholangiography.

3848 COMPLICATION WITH CONTRAST MEDIUM IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATICOGRAPHY. (Ger.) Gmelin, E.; Kramann, B.; Weiss,

H. D. (Institut fur Rontgendiagnostik, Techn. Universitat, Ismaninger Str. 22, D-8000 Munich 80, W. Germany). *Munch. Med. Wochenschr.* 119(44):1439-1440; 1977.

In a series of over 2,000 endoscopic retrograde cholangiopancreatographies, allergic shock to the contrast medium (Conray 60) was observed in a 60-yr-old woman. The cholangiopancreatography was performed in a technically correct manner. The patient developed circulatory collapse 10 min after the administration of the contrast medium. Slow recovery was achieved in about 15 min by cortisone treatment and blood substituent infusion. The patient was fully responsive 30 min after the onset of the shock, and she could be discharged in good condition in 24 hr. This observation indicates that patients with known allergy to contrast media should undergo endoscopic retrograde cholangiopancreatography only if other examinations were unsuccessful and diagnostic evaluation is of vital interest.

3849 THE PEPTIDE PABA TEST. (Ger.) Bornschein, W. (II. Med. Klinik, TU Munchen, Ismaningerstrasse 22, 8 Munich 80, W. Germany). *Fortschr. Med.* 95(42):2559-2564; 1977.

The chymotrypsin specificity of the synthetic peptide *N*-benzoyl-L-tyrosyl-*p*-aminobenzoic acid was tested *in vitro* and *in vivo* in 52 subjects, 34 of whom had normal pancreatic function to evaluate the peptide's usefulness as a screening tool for pancreatopathy. Comparative kinetic tests with bovine chymotrypsin and human activated pancreatic juice, as well as clearance tests with *p*-aminobenzoic acid (PABA), demonstrated that this peptide is suitable for an indirect pancreatic function test. In the clinical tests, PABA was administered p.o. (150 mg in 250 ml water), and the PABA level was determined in 9-hr urine. Both with and without pancreatic stimulation by Lundh's test meal, a significant ($p<0.01$) difference was found in the urinary clearance between patients with exocrine pancreatic insufficiency and subjects with normal pancreas. There were 8.8% false-positive and 6.2% false-negative test results. The 6-hr urinary PABA excretion, expressed in percentage of the dose administered, showed good correlations with the 1-hr amount of chymotrypsin in the pancreozymin-cholecystokinin-secretin test and with the fecal chymotrypsin level. These preliminary results indicate that the PABA test is suitable as a screening method in pancreatopathy.

3850 STUDY ON THE EXOCRINE PANCREATIC FUNCTION BY THE ORAL ADMINISTRATION OF N-BENZOYL-L-TYROSYL-PARA-AMINOBENZOIC ACID. (Eng.) Kato, K.; Izumiyama, S.; Sakakura, M.; Hirayama, A.; Ishii, K. (Asahikawa Medical Coll., 3-11, Kaguraoka, Kagura-cho, Asahikawa, Hokkaido, 078-11, Japan). *Gastroenterol. Jpn.* 12(4):289-292; 1977.

The value of *N*-benzoyl-L-tyrosyl-*p*-aminobenzoic acid (Bz-ty-PABA) in the diagnosis of exocrine pancreatic insufficiency was studied in 11 controls, 10 patients with chronic pancreatitis, 7 patients with diabetes mellitus, and 6 patients with liver cirrhosis who received Bz-ty-PABA (500 mg) p.o. The cumulative 6-hr recovery rate of PABA in the urine was significantly lower ($p<0.005$) in patients with chronic pancreatitis (49.1 ± 10.1%), diabetes mellitus (50.4 ± 20.4%), and liver cirrhosis (52.5 ± 13.0%) than in the control group (79.5 ± 12.0%). This test is useful in the diagnosis of pancreatic exocrine insufficiency, especially in chronic pancreatitis.

3851 PURIFICATION, PARTIAL CHARACTERIZATION, AND CLINICAL EVALUATION OF PANCREATIC ONCOFETAL ANTIGEN. (Eng.) Gelder, F. B.; Reese, C. J.; Moossa, A. R.; Hall, T.; Hunter, R. (Dept. Pathology, Univ. Chicago, Box 414, 950 East 59th St., Chicago, IL 60637). *Cancer Res.* 38(2):313-324; 1978.

The purification and partial characterization of a putative pancreatic oncofetal antigen is described. Human fetal tissue (18- to 20-week gestation) and normal and cancerous adult tissues were examined. Pancreatic oncofetal antigen was shown to be a glycoprotein with a molecular weight between 800,000 and 900,000 daltons, which migrated in the α_2- to β-region on electrophoresis. It was found in fetal pancreas and pancreatic cancer tissue but was not found in normal adult pancreas. Highly purified material migrated as a single band during polyacrylamide gel electrophoresis and caused immunized rabbits to produce monospecific antibody without absorption. Pancreatic oncofetal antigen was clearly different from carcinoembryonic antigen, other known tumor-associated antigens, acute-phase reactants, and normal serum proteins. In addition, a quantitative rocket immunoelectrophoresis assay sensitive enough to detect pancreatic oncofetal antigen in the serum of most patients was developed and used to monitor the purification of pancreatic oncofetal antigen and to evaluate its clinical application. Assays for pancreatic oncofetal antigen were carried out on three panels of sera from different sources. Pancreatic oncofetal antigen was found in the sera of most individuals; however, the highest absolute levels and the highest frequency of elevated levels were found in sera of patients with pancreatic carcinoma. Elevated levels of pancreatic oncofetal antigen were also observed in the serum of some patients with lung, stomach, colon, biliary tract, and breast carcinomas, as well as in the serum of some pregnant women and other individuals with certain benign conditions. The spectrum of patients who have elevated levels of pancreatic oncofetal antigen in their serum is quite different from that found with carcinoembryonic antigen or other known tumor markers. Serial assays were performed on the sera of several patients with cancer of the pancreas; the results suggest that measurement of pancreatic oncofetal antigen may be valuable in monitoring the course of pancreatic cancer.

GASTROINTESTINAL DISEASES

ESOPHAGUS

3905 pH-METRIC INVESTIGATION OF GASTROESOPHAGEAL REFLUX FOLLOWING PENTAGASTRIN ADMINISTRATION. (Ger.) Pflucke, F.; Arendt, R. (Klinik fur Innere Medizin des Bereichs Medizin, Wilhelm-Pieck-Universitat, Ernst-Heydemann-Strasse, DDR-25 Rostock, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 37(3):117-122; 1977.

Gastroesophageal reflux was measured by pH-metric tests in 36 patients, including 16 with acute reflux symptoms, 6 with mild symptoms, and 14 without symptoms. The tests were conducted in the morning 24 hr after administration of medication and 12 hr after intake of food. The patients swallowed a glass electrode after it had been determined that the pH was <2.0 in their stomachs; pH activities in the distal esophagus were monitored for 1 hr. The patients were then given pentagastrin (6 μg/kg body weight, s.c.) and monitored for 1 hr. Reflux frequency was determined by the number of times the pH level fell below 4; total reflux duration was the total of all separate refluxes. Spontaneous gastroesophageal reflux was observed in six patients during the tests. Of 30 patients without reflux before pentagastrin administration, 19 demonstrated gastroesophageal reflux after pentagastrin; reflux was absent in 11 patients. Pentagastrin appears to stimulate reflux in patients with common reflux problems, but is not effective in patients free of symptoms. Pentagastrin can be diagnostically useful in pH-metric reflux tests.

STOMACH

3929 QUANTITATIVE DETERMINATION OF PYLORIC REGURGITATION IN RESPONSE TO INTRADUODENAL BOLUS INJECTION. (Eng.) Rokkjaer, M.; Marqversen, J.; Kraglund, K.; Petersen, J. B. (Kommunehospitalet, Aarhus, Denmark). *Scand. J. Gastroenterol.* 12(7):827-832; 1977.

Duodeno-gastric regurgitation was measured quantitatively in patients using ^{99m}technetium-colloid and external scanning. The median reflux for 32 patients with type I gastric ulcer was 14% (range, 3-100%), which was significantly ($p<0.05$) higher than the median reflux of 4% (range, 1-13%) for 9 controls and the median reflux of 5% (range, 0-16%) for 9 duodenal ulcer patients. There was no significant difference between the reflux in the control and duodenal ulcer groups. When 14 different examinations were evaluated twice, the standard deviation of the differences between the two interpretations was 5.88% with a 95% confidence interval of 4.30-9.27%, which differences were not significant. Thus, the test had fairly good reproducibility. When the reflux test was performed in eight patients before and after antrectomy, a large variance and an absence of a significant difference between the two tests were observed. Although the two tests before and after antrectomy in each of the eight patients differed considerably, a larger reflux was found through the relatively large stoma of a gastro-duodenostomy in only half of the patients after the operation.

3930 EFFECT OF SODIUM BICARBONATE ON ASPIRIN-INDUCED DAMAGE AND POTENTIAL DIFFERENCE CHANGES IN HUMAN GASTRIC MUCOSA. (Eng.) Bowen, B. K.; Krause, W. J.; Ivey, K. J. (Harry S Truman Veterans Admin. Hosp., Columbia, MO 65201). *Br. Med. J.* 2(6094):1052-1055; 1977.

A study was performed to determine whether a small amount of sodium bicarbonate (equivalent to one-

hird of a teaspoonful of baking soda) could pro-
ect against the microscopic gastric mucosal dam-
ge known to be produced by the ingestion of two
spirin tablets in 100 ml of fluid. Sequential
astric biopsy specimens were taken from 15 healthy
ubjects before, during, and after the intragastric
nstillation of one of the following isotonic sol-
tions: saline, sodium bicarbonate, 600 mg aspirin
uspended in sodium bicarbonate, and aspirin sus-
ended in saline. On a separate day, the same
olutions were instilled, but gastric transmucosal
otential differences were monitored. Light mi-
roscopy and scanning electron microscopy of the
iopsy specimens showed occasional mucous degran-
lation of mucosal surface cells, but no cell
amage during instillation of sodium bicarbonate.
ight microscopy studies 10 min after instillation
f aspirin in saline showed damage in 20% of sur-
ace cells, with focal areas of cellular disrup-
ion and microscopic erosions, but only 3.4% of
ells were damaged after aspirin in bicarbonate,
nd there were no erosions. Electron microscopy
howed a damaged honeycomb appearance of surface
pithelium after aspirin in saline and a normal
obblestone appearance after aspirin in bicarbonate.
spirin dissolved in bicarbonate failed to induce
he usual fall in potential difference. These
indings indicate that sodium bicarbonate in
mounts equivalent to one-third of a teaspoonful
f baking soda protects the gastric mucosa against
spirin-induced damage and prevents the usual fall
n potential difference after aspirin ingestion.

931 THE HEATER PROBE: A NEW ENDOSCOPIC METHOD
FOR STOPPING MASSIVE GASTROINTESTINAL
LEEDING. (Eng.) Protell, R. L.; Rubin, C. E.;
uth, D. C.; Silverstein, F. E.; Terou, F.; Dennis,
.; *et al.* (Dept. Medicine RG-20, Univ. Washington,
eattle, WA 98195). *Gastroenterology* 74(2, Part
):257-262; 1978.

heater probe that can be passed via an endoscope
nd that can apply pressure and heat simultaneously
o a bleeding vessel was developed. A 6.4-mm dia-
eter prototype and a 3.2-mm diameter working model
f this device were tested for efficacy in stopping
assive bleeding in experimental canine gastric ul-
ers. Randomized, internally controlled experiments
ere carried out at laparotomy in heparinized dogs
sing standard-sized gastric ulcers made and treat-
d via an ample gastrotomy. In acute experiments,
he heater probe stopped bleeding from all treated
lcers, whereas all untreated control ulcers con-
inued bleeding. In chronic studies performed at
terile laparotomy, the depth of injury produced
y heater probe coagulation was systematically
valuated; dogs were killed at intervals from 1 week
o 1 month. No perforations occurred, but histo-
logical injury was evident extending from the ul-
er base to the serosa in 7 of the 18 ulcers treat-
d with the 6.4-mm probe and in 2 of the 30 ulcers
reated with the 3.2-mm probe. In a preliminary
ndoscopic experiment, the 3.2-mm probe stopped
leeding in 18 of 19 acute experimental ulcers.
istological evidence of injury extending to the
erosa occurred in six instances; no perforations
occurred. The efficacy in stopping bleeding with this method is satisfactory, but the depth of injury should be reduced before it is applied to humans.

3932 ENDOSCOPIC LASER TREATMENT. III. DEVELOPMENT AND TESTING OF GAS-JET-ASSISTED ARGON LASER WAVEGUIDE IN CONTROL OF BLEEDING EXPERIMENTAL ULCERS. (Eng.) Silverstein, F. E.; Protell, R. L.; Gulacsik, C.; Auth, D. C.; Deltenre, M.; Dennis, M.; *et al.* (Dept. Medicine, RG-20, Univ. Washington, Seattle, WA 98195). *Gastroenterology* 74(2, Part 1):232-239; 1978.

A new argon laser system for the treatment of ulcer bleeding is described, and its efficacy and safety were evaluated in the treatment of experimental canine gastric ulcers. The system consists of a catheter that can be inserted via an endoscopic biopsy channel to deliver a jet of CO_2 coaxially with an argon laser beam. The efficacy of this system in stopping bleeding was tested in two acute experiments at laparotomy in heparinized dogs using a gastric ulcer model. At 7 W of power, the gas jet-assisted laser proved 100% effective in stopping bleeding with an average of three 5-sec exposures, as compared to the same laser without added CO_2, which required an average of eleven 5-sec exposures. Furthermore, the 7-W laser without added CO_2 did not stop all ulcer bleeding. The safety of the CO_2 laser system was tested in a chronic experiment at sterile laparotomy using the same ulcer model. No ulcer treated with the 7-W gas jet-assisted argon laser showed histologic evidence of full thickness injury. When the efficacy of various wattages of the gas jet-assisted laser in stopping bleeding from the ulcer model was tested, the wattages used in this series of experiments and in previous experiments proved to be in the efficacious range. It is concluded that CO_2 added coaxially to a 6- to 7-W argon laser increases the efficacy of coagulation while reducing the depth of injury.

3933 GRADE OF INVASION OF GASTRIC CANCER AT THE TIME OF DIAGNOSIS. (Spa.) Perez Mota, A.; Villalobos Gamez, J. M.; Alberdi Frias, J. M.; Linares Garcia, F.; Moreno Gonzalez, E.; Hidalgo Pascual, M.; *et al.* (Servicio-Escuela de Enfermedades Digestivas del Instituto Nacional de Prevision, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 51(4):353-362; 1977.

The diagnostic and clinical aspects of gastric cancer are described on the basis of 68 cases. It was possible to diagnose 98% of all cases by the combination of x-raying, biopsy, endoscopy, and cytology. Dyspeptic syndrome was found in 16 patients (average duration 8.8 months), ulcerous syndrome in 52 (average duration 10.3 months), neoplastic syndrome in 60, and macroscopic hemorrhage in 14. The tumor was localized in the antrum in 55% of all cases, in the corpus of the stomach in 25%, and in the magenblase in 12.5%; practically total invasion of the stomach was found in 7%. Adenocarcinoma was diagnosed in 60 cases (highly differentiated tumor in 27 cases, medium differentiated tumor in 12, and tumor of low degree of differentiation in 21). Calix-like metaplasia was seen in 22 of these 60 cases. Signet-ring cell tumor was found in eight cases. Solitary or multiple metastases were found at diagnosis in 58 patients: lymph node metastases accounted for 25.4%; hepatic metastases for 17.6%; pancreatic metastases for 15.6%; vascular metastases for 7.8%; mesenteric metastases for 13.7%; diaphragmatic, peritoneal, colonic, and esophageal metastases for 3.9%; and splenic and retroperitoneal metastases for 1.9%. The tumor invaded the serosa in 6 of the 10 metastasis-free patients, and it was limited to the mucosa and submucosa in the 4 others. The findings indicate the great value of complex screening in high-risk groups.

3934 PRIMARY GASTRIC STUMP CARCINOMA. (Ger.) Wolf, O.; Pannenborg, G.; Voigtsberger, P. (Chirurgische Klinik, Medizinische Akademie, Nordhauser Str. 74, DDR-50 Erfurt, E. Germany). *Zentralbl. Chir.* 102(19):1183-1187; 1977.

The diagnosis and treatment of gastric stump carcinoma are reviewed. Gastric or duodenal resection was performed in 3,476 patients during the 1956-1975 period, among whom 35 patients had carcinoma of the gastric stump. The latent period was 6-38 yr, averaging 21 yr. Epigastric pains, loss of weight, emesis, loss of appetite, nausea, and eructation were the most frequent symptoms. Exploratory laparotomy was performed or endoprosthesis was inserted in 25 cases; radical surgery was possible in only 10 cases. The postoperative mortality was 11/35; 23 patients survived 2-15 months (average, 5.3 months). The 5-yr cure rate was 1/35. The findings indicate that prognosis can be improved only be earlier diagnosis.

3935 STUDY OF HUMORAL IMMUNITY AND GASTRIC FUNCTION IN SUBJECTS WITH VITILIGO. (Ita.) Farini, R.; Veller, C.; Di Mario, F.; Trovo, M.; Borrelli, A.; Meani, A.; *et al.* (Istituto di Clinica Medica I Univ., Padova, Italy). *Minerva Dermatol.* 111(5):271-278; 1976.

Humoral immunity and gastric function were studied in 31 patients with vitiligo. Concomitant diseases included duodenal ulcer in two patients, gastritis in one, and cholelithiasis in two. The subjective complaints included dyspepsia in seven patients, epigastric pains in two, and biliary colic in one. The gastrin level was significantly higher in the patients than in 39 healthy controls (47 ± 26 pg/ml versus 32 ± 20 pg/ml, $p<0.005$). There were no significant differences between the patients and the controls in terms of the basal acid output, maximal acid output, and the peak half-hour acid output, but the values measured in the patients were at the upper limit of the normal range. Hypochlorhydria (maximal acid output below 4 mEq/hr) was found in three patients. Disease associations and biohumoral and immunological alterations were more frequent in patients with hypergastrinemia and/or circulating autoantibodies. There is, however, no clear evidence supporting the immunological pathogenesis of vitiligo.

Peptic Ulcers

3965 CHRONIC GASTRITIS AND PEPTIC ULCER. (Eng.) Zaterka, S.; Vieira, F. E.; Pfuhl Neves, D.; da Silva, E. P.; Carneiro Leao, G.; Bettarello, A. (Medical Sch., Univ. Sao Paulo, Rua Estados Unidos, 1470, Sao Paulo, Brazil). *Acta Hepatogastroenterol. (Stuttg.)* 24(5):381-385; 1977.

The incidence of gastritis was determined in 51 patients with duodenal ulcer and 46 with gastric ulcer, and the relationship between gastritis and the location of the ulcer was studied. Six biopsies (3 from the antrum and 3 from the body) were obtained from each patient under direct vision at endoscopy. Chronic gastritis was classified according to the grade of inflammation (slight, moderate, or intense) and its location (antritis or pangastritis). In gastric ulcer, the relationship between frequency of chronic gastritis and the site of the ulcer (antrapyloric, at the angulus, body of the stomach) was also established. Antritis was as frequently observed in duodenal ulcer (94%) as in gastric patients (96%), but severe inflammation of the antrum was higher in gastric ulcer (43%) than in duodenal ulcer (17%). Chronic gastritis of the gastric body was always accompanied by antritis in both gastric and duodenal ulcer; gastritis was observed in 63% of the former group and 37% of the latter. Severe inflammation of the glandular portion of the stomach occurred in only one patient with duodenal ulcer (2%) and in seven with gastric ulcer (15%). No relationship between the site of gastric ulcer and the frequency of chronic gastritis was observed.

SMALL INTESTINE

3990 FACTORS INFLUENCING SMALL BOWEL CHANGES IN DERMATITIS HERPETIFORMIS. (Eng.) Roberts-Thomson, I. C.; Stevens, D. P.; Michel, B.; Braun, W. E.; Morris, P. J.; Wall, A. J.; *et al.* (Royal Melbourne Hosp., Victoria 3050, Australia). *Aust. N.Z. J. Med.* 7(4):356-362; 1977.

Factors influencing small bowel morphology in dermatitis herpetiformis (DH) were investigated by comparing 9 patients with DH and normal small bowel biopsies with 18 patients with DH and abnormal small bowel biopsies. The mean age of the patients with morphological changes in small bowel (38 yr) was significantly lower ($p<0.001$) than that of the patients with normal bowel mucosa (60 yr). Histocompatibility locus antigen (HLA) typing confirmed the high frequency of HLA-B8 in DH (64%), but HLA-B8 was unrelated to the presence or severity of small bowel lesions. Four patients had diarrhea with progressive weight loss or abdominal cramps subsequently responsive to gluten withdrawal. In this subgroup, serum IgG and IgM levels were significantly lower than in patients with normal small bowel mucosa. Small bowel involvement appeared to be independent of the duration and severity of skin disease, and the deposition of immunoglobulin and complement (C3) in the dermal papillae of skin adjacent to skin lesions. The relation between age and small bowel morphology in DH has not been noted previously.

SMALL INTESTINE

Malabsorption

4003 ASSOCIATION OF PRECIPITINS AND COELIAC DISEASE. (Eng.) Kavai, M.; Csorba, S.; Szabolcs, M.; Jezerniczky, J.; Fesus, L.; Szabo, B. (Univ. Medical Sch., 4004 Debrecen, Hungary). *Acta Allergol. (Kbh.)* 32(6):395-405; 1977.

The blood antibody types were studied in the sera of 28 celiac patients and of controls in an effort to understand the induced reaction resulting in gluten intolerance in this disease. Four fractions (A, B, C, and D) were isolated from the cold (2-4 C) aqueous extract of wheat flour by Sephadex G-75 column fractionation. Fraction A (molecular weight, 36,000-61,000 daltons) reacted as an antigen with the sera of celiac patients. Its molecular weight and amino acid composition (particularly, the high quantities of glutamic acid and proline) were similar to those of gliadin. IgE exceeded the normal value only in 3 patients (601-1,000 IU/ml), whereas 14 patients had 200-600 IU IgE/ml and 11 patients had 100-200 IU IgE/ml. The heat-inactivated sera of the patients formed a precipitate with the homologous antigen in higher dilutions than did the sera from controls. On the basis of *in vitro* rat mast cell sensitizing capacity of the patients' sera, specific antigliadin IgE was only found in one out of the seven patients tested, and this was a patient with elevated IgE level. Sera containing high quantities of antibody (as shown by precipitation and passive hemagglutination assays) were compared before and after absorption by anti-IgG and anti-IgA for their ability to form precipitates with antigen (gliadin) and anti-IgG in immunodiffusion assays. Prior absorption by anti-IgG was more effective than prior absorption by anti-IgA in reducing the reaction of the sera with gliadin. The results are consistent with the conclusion that antibody produced against wheat-derived protein circulating in serum belongs mainly to the IgG class.

4004 IMMUNOLOGICAL ABNORMALITIES IN COELIAC DISEASE AND THEIR RESPONSE TO DIETARY RESTRICTION. I. SERUM IMMUNOGLOBULINS, ANTIBODIES AND COMPLEMENT. (Eng.) Ratnaike, R. N.; Wangel, A. G. (Queen Elizabeth Hosp., Woodville, South Australia 5011, Australia). *Aust. N.Z. J. Med.* 7(4):349-352; 1977.

In an effort to gain information on whether the immunological changes found in celiac disease are related to its pathogenesis, 23 patients with this disease were studied while on a normal diet and again after a mean period of 15 months on a gluten-free diet. Serum levels of IgG, IgA, and IgM, total hemolytic complement, complement component C3, serum autoantibodies, and precipitins to dietary proteins were compared with those in age- and sex-matched controls. There was considerable individual variation, but as a group, patients on a normal diet had raised IgA and low IgM levels and an increased prevalence of antibody to reticulin, smooth muscle, and dietary protein. These abnormalities disappeared during the period of dietary restriction, suggesting that they are disease epiphenomena rather than primary pathogenetic factors.

4005 IMMUNOLOGICAL ABNORMALITIES IN COELIAC DISEASE AND THEIR RESPONSE TO DIETARY RESTRICTION. II. IMMUNOGLOBULIN CONTAINING CELLS, IMMUNOGLOBULINS AND DIETARY ANTIBODIES IN THE SMALL BOWEL. (Eng.) Ratnaike, R. N.; Wilson, J.; Wangel, A. G. (Queen Elizabeth Hosp., Woodville, 5011 South Australia, Australia). *Aust. N.Z. J. Med.* 7(4): 353-355; 1977.

The numbers of immunoglobulin-containing cells in jejunal mucosa were determined in 29 patients with untreated celiac disease and 28 controls. The patients had significantly increased numbers of IgM-containing cells in comparison with controls ($p < 0.001$). Seven patients were studied again after 12 months on a gluten-free diet and showed a significant reduction in the number of IgM-containing cells in comparison with that when they were on the normal diet ($p < 0.025$). The increase noted in untreated patients is therefore likely to be a manifestation of the disease rather than a primary abnormality of etiological significance.

4006 LACTOSE INTOLERANCE, DETECTED BY THE HYDROGEN BREATH TEST, INFANTS AND CHILDREN

WITH CHRONIC DIARRHEA. (Eng.) Maffei, H. V. L.; Metz, G.; Bampoe, V.; Shiner, M.; Herman, S.; Brook, C. G. D. (Faculdade de Ciencias Medicas e Biologicas, 18600 Botucatu, Sao Paulo, Brazil). *Arch. Dis. Child.* 52(10):766-771; 1977.

The value of the hydrogen breath test (HBT), adapted for use in young infants and children, in the diagnosis of lactose malabsorption was assessed in 23 children aged 2.5 months to 13 yr with chronic diarrhea and 6 patients without diarrhea. A further eight children with proven or suspected celiac disease were also investigated. The HBT was compared with the histology of the jejunal mucosa, mucosal lactase estimations, a lactose tolerance test, symptoms during the test, and follow-up after starting a lactose-free diet. The six patients without diarrhea showed no evidence of hypolactasia and the hydrogen concentration on the HBT was below 7 ppm, a level considered to be clinically nonsignificant. Twelve of the 23 patients with diarrhea had a breath H_2 concentration greater than 24 ppm, and this correlated well with their clinical symptoms during or after the test and with the remission of the diarrhea after lactose withdrawal. Of the remaining 11 patients with diarrhea whose breath H_2 concentration was lower than 25 ppm, symptoms did not improve when a lactose-free diet was started in 3, while a further 4 improved on a full diet. There was poor correlation between the HBT and the findings on the jejunal mucosal specimens. All but one of the celiac patients had an HBT less than 20 ppm, and none of these required lactose withdrawal for remission of symptoms. The HBT is a noninvasive test particularly suitable for outpatients, and it gives a useful prognostic guide to the efficacy of lactose-free diet in the treatment of chronic diarrhea in children.

4007 GASTRIC EMPTYING OF LACTOSE AND MILK IN SUBJECTS WITH LACTOSE MALABSORPTION. (Eng.) Welsh, J. D.; Hall, W. H. (Univ. Oklahoma Health Sciences Center, P.O. Box 26901, Oklahoma City, OK 73190). *Am. J. Dig. Dis.* 22(12):1060-1063; 1977.

Gastric emptying tests with 750-ml meals of glucose in water, lactose in water, plain milk, and chocolate milk were carried out in six lactose absorbers (LA) and five lactose malabsorbers (LM). The glucose and lactose meals emptied in a similar fashion in LA and LM subjects with a significant decrease in gastric emptying as the osmolarity of the meals was doubled. If the data were normalized by dividing lactose emptying by the emptying of glucose meals of twice the osmolality in each individual, the lactose malabsorbers emptied significantly more lactose ($p<0.01$). Both LA and LM subjects emptied comparable amounts of milk meals having similar osmolarity. Chocolate milk, which had a higher osmolality than plain milk, emptied more slowly than plain milk in both groups, and this difference was significant ($p<0.01$) in the LM group. In LM individuals, chocolate milk, in addition to fermented dairy products, should be tried as alternatives to total abstinance from dairy products.

4008 PRIMARY ABDOMINAL LYMPHOMA: PRESENTING MANIFESTATION OF CELIAC SPRUE OR COMPLICATING DERMATITIS HERPETIFORMIS. (Eng.) Freeman, H. J.; Weinstein, W. M.; Shnitka, T. K.; Piercey, J. R. A.; Wensel, R. H. (Dept. Medicine, Univ. Alberta, Edmonton, Alberta T6G 2G3, Canada). *Am. J. Med.* 63(4):585-594; 1977.

The association between primary abdominal lymphoma and celiac sprue or dermatitis herpetiformis was examined. During a 4-yr period, seven patients with abdominal lymphoma were found on subsequent investigation to have celiac sprue or the closely linked disorder, dermatitis herpetiformis. Five patients had a small intestinal lymphoma, one had a gastric lymphoma, and one had a retroperitoneal lymphoma. Histologically, six of the seven tumors were of a diffuse histiocytic type, and one was undifferentiated. In four patients, the ulcerating small intestinal lymphoma was initially misinterpreted as "benign ulcerative nongranulomatous jejunoileitis," a condition also reported to complicate celiac sprue. In several patients, the associated celiac sprue was clinically occult and could readily have been missed. The celiac sprue was fully responsive in five of the patients who were treated with a gluten-free diet. These studies suggest that celiac sprue and abdominal lymphoma occur together more often than is currently appreciated. The frequency of this association may be overlooked for two reasons: the associated celiac sprue is sometimes mild and may remain undetected, and early ulcerative intestinal lymphoma may be mistaken for benign ulcerative nongranulomatous jejunoileitis. Patients with abdominal lymphoma should be investigated for celiac sprue and for dermatitis herpetiformis.

4009 INTESTINAL LYMPHOMA ASSOCIATED WITH MALABSORPTION. (Eng.) Isaacson, P.; Wright, D. H. (Southampton Univ. Hosp., Southampton SO9 4XY, England). *Lancet* 1(8055):67-70; 1978.

Clinical findings in 18 patients with small intestinal lymphoma associated with villous atrophy and crypt hyperplasia of uninvolved mucosa are presented. Most patients presented with acute obstruction or perforation preceded by abdominal pain and weight loss. However, malabsorption, thought to be adult celiac disease, preceded the diagnosis of lymphoma in five cases. The lymphomas were composed of malignant histiocytes and were classified on morphological grounds as malignant histiocytosis. Immunohistochemical techniques revealed that all major immunoglobulin classes were present within malignant cells of single tumors. Characterization of this group of lymphomas as a specific entity should help in the further understanding of the relationship of malabsorption and lymphoma and in the rationalization of treatment.

4010 MACROGLOBULINEMIA AND MALABSORPTION. (Eng.) Tubbs, R. R.; McLaughlin, J. P.; Winkelman, E. I.; Deodhar, S. D.; Hewlett, J. S. (Cleveland Clinic, Cleveland, OH). *Cleve. Clin. Q.* 44(4):189-191; 1977.

Intestinal involvement in Waldenstrom's macroglobulinemia (IgM monoclonal [kappa] gammopathy) in a 58-yr-old woman is presented because the phenomenon is rare in this disease. The patient had been treated for anemia (symptoms of fatigue, weakness, and weight loss) with low-fat diet, prednisone (30 mg/day), and thyroid USP (3 grains/day), had undergone an exploratory laparotomy that disclosed lymphangiectasia of the intestinal lymphatics and mesenteric lymph nodes, and was treated with cyclophosphamide (50 mg p.o. twice daily) and prednisone (60 mg p.o. every other day) to resolve malabsorption, splenomegaly, IgM monoclonal (kappa) gammopathy, anorexia, and weight loss. The patient was hospitalized for pneumonia (resolved with cephalothin) and then for hyperpyrexia, athralgias, visual disturbances, anemia, and leukopenia; *Staphylococcus aureus* bacteremia was found. The patient died despite reverse isolation, several transfusions, and antibiotic therapy with multiple antimicrobial agents. Histologically, at necropsy, the gallbladder contained a moderate mucosal and submucosal chronic inflammatory infiltrate. The jejunum, mesentery, and mesenteric lymph nodes demonstrated a marked lymphectasia. Additionally, necropsy tissues revealed severe organizing bronchopneumonia and focal myocardial fibrosis. A mixed diffuse infiltrate of mature lymphocytes, plasma cells, plasmacytoid lymphocytes, and occasional lymphoid cells with Dutcher bodies was present in lung, bone marrow, spleen, and lymph nodes. Deposition of all immunoglobulin heavy chains and both light chains within the inspissated material in dilated submucosal lymphatics and intestinal lacteals was shown. There was no extracellular deposition of IgM within the small bowel other than within the dilated lymphatic channels. It appears that mucosal deposition of the monoclonal immunoglobulin is the primary pathogenetic mechanism, and that obstruction and stasis of lymphatic circulation due to effacement of mesenteric lymph nodes by the malignant infiltrate are of primary importance in the pathogenesis of the lesion.

4011 PATHOPHYSIOLOGY AND CLINICAL ASPECTS OF MALASSIMILATION. (Ger.) Classen, M.; Hoffmann, L. (I. Medizinische Abteilung, Allgemeines Krankenhaus Barmbek, Rubenkamp 148, D-2000 Hamburg 60, W. Germany). *Med. Klin.* 72(13):533-541; 1977.

LARGE INTESTINE

4014 APPENDICEAL ABSCESS REVISITED. (Eng.) Bradley, E. L., III; Isaacs, J. (Emory Univ. Sch. Medicine, 69 Butler St. SE, Atlanta, GA 30303). *Arch. Surg.* 113(2):130-132; 1978.

The occurrence of appendiceal abscess was reviewed for the period 1962-1976. Two percent of 2,621 patients with acute appendicitis developed appendiceal abscess. Sixty-one of 68 patients underwent surgical drainage of the abscess, with a 28% complication rate. Interval appendectomy was performed in 42 cases, with a 19% complication rate. Two patients died. These rates do not differ appreciably from those reported during the pre-antibiotic era. Recurrent appendicitis developed in only 1 of 13 patients not undergoing interval appendectomy during a follow-up period averaging 5 yr. Interval appendectomy should be withheld only in those poor-risk patients in whom the 10% to 20% incidence of recurrent appendicitis seems the smaller risk. Although the number of patients developing appendiceal abscess represents a decline in frequency from earlier studies, further decreases in incidence could be effected by increased patient education.

4015 POLICY OF LOCAL EXCISION FOR EARLY CANCER OF THE COLORECTUM. (Eng.) Morson, B. C.; Bussey, H. J. R.; Samoorian, S. (St. Mark's Hosp., London, England). *Gut* 18(12):1045-1050; 1977.

The results of local excisions performed over a 25-yr period in 143 patients with cancer of the rectum and distal colon are described to evaluate a policy of local excision or total biopsy for certain selected colorectal cancers. Many of the lesions presented as malignant polyps. All procedures were followed by a thorough histological examination to evaluate the need for further radical operation. The grade of the malignancy was low in 60 cases, average in 77, and high in 6. The tumor diameter was <2 cm in 86 cases, 2-3 cm in 26, 3-4 cm in 15, and >5 cm in 5. In 115 patients, the carcinoma did not spread beyond the submucosa of the rectal or colonic wall. In 20 cases, it penetrated into the muscularis propria and in 7 cases it reached the extramural tissue. In 102 patients, the local excision was regarded as histologically complete with 91/102 accomplished by local excision only; recurrence was observed in only 3 of the 91 patients and one of these must be regarded as a failure of the policy. In eight cases, the local excision was followed by a major operation because the local excision was suspected to be incomplete; only two patients from this group died 2 and 3.5 yr after treatment with evidence of recurrence, and the evidence indicates that these were not policy failures. In 14 of 18 patients with doubtfully complete local excision, no further operation was performed for various reasons; there was evidence of recurrence in only 2 cases, and these were classed as policy failures. In four patients with doubtfully complete local excision, a major operation was performed that showed residual tumor growth at the site of local excision in two cases, moderately differentiated carcinoma spreading into muscularis propria or submucosa in two cases, and no residual tumor in the other two cases. In 23 cases the local excision was regarded as histologically incomplete; 14/23 had had palliative local excisions and were not subjected to further surgical treatment due to various contraindications; only 5 recurrences were observed. Residual tumor growth was found in only three of the nine patients who had a major operation following incomplete local excision. The crude and corrected 5-yr survival rates for patients with complete, doubtfully complete, and incomplete local excisions were 82% and 100%, 64% and 96%, and 57% and 83%, resp. Because of the good results, local excision should be regarded as an established alternative to partial colectomy, anterior resection, and abdominoperineal excision in carefully selected patients.

4016 TUMOR-HOST RELATIONSHIPS IN COLORECTAL CARCINOMA.

(Eng.) Syrjanen, K. J.; Hjelt, L. H. (Jorvi Hosp., 02740, Espoo 74, Finland). *Dis. Colon Rectum* 21(1):29-36; 1978.

Histological studies of colorectal carcinoma, its surrounding stroma, and regional lymph nodes with special reference to the morphology of possible tumor-host relationships were performed in 87 consecutive patients and 5-year follow-ups completed for 74 patients. The tumors were graded according to the nuclear structure as slight nuclear atypia (grade I), moderate atypia (grade II), strong atypia (grade III), and profound atypia (grade IV). Tumor-derived mucus content was estimated as low, moderate, or high. The stromal lymphocyte and mast cell reactions and the mast cell reaction in the nodes were graded weak, moderate, or strong. Lymph node follicular hyperplasia was classified from 0 to 4 based on the number of follicles seen. Paracortical activity was graded into three classes on the basis of the small lymphocyte content, the height of the endothelial cells of the postcapillary venules, and the occurrence of lymphocytes in their lumena. Sinus reactions were classified as sinus histiocytosis, degenerative sinus histiocytosis, nonspecific sinus reactions, and no sinus reactions. The extent of metastases was graded from 1 to 4 according to the node area invaded by the tumor. A direct correlation was found between tumor grade and the 5-yr prognosis, although the sample size was too small for statistical analysis. Five-year survival was 100%, 50.0%, 36.7%, and 16.7% for patients with tumors graded I-IV, resp. Metastases were more frequent in patients with grade IV and grade III tumors (50% and 43.5%, resp.) than in those with grade II or grade I tumors (7.1% and 0.0%, resp.), and prognosis appears poorer for those with nodal metastases. Regardless of tumor grade, 5-yr survival rates seem to be independent of the mucous content. There appears to be a direct positive correlation between stromal lymphocyte reaction and the 5-yr survival rate. A similar correlation, although not so strong, was observed between the prognosis and the mast cell reaction. Follicular hyperplasia of lymph nodes did not correlate with the appearance of nodal metastases. The latter was, however, inversely correlated with paracortical activity. Sinus histiocytosis was never associated with nodal metastases. It is concluded that complex factors of both tumor and host origin modify local invasiveness of colorectal carcinoma and greatly affect the prognosis.

4017 CHEMOPROPHYLAXIS FOR PATIENTS WITH POST-OPERATIVE HIGH RISK COLORECTAL CANCER.

(Eng.) Li, M. C.; Ross, S. T. *In: Adjuvant Therapy of Cancer.* (Amsterdam: Elsevier/North-Holland Biomedical Press): 273-277; 1977.

The effectiveness of short-term fluorouracil (FU) chemoprophylaxis begun 4-6 weeks after curative surgery was evaluated in 183 patients with Duke's class B or C colorectal cancer who were operated on between 1965 and 1970. The controls were a group of similar patients operated on between 1960 and 1965 but who did not receive the drug. Patients <65 yr old, >60 kg in weight, or in good nutritional state received 1,000 mg FU i.v. push on day 1, 500 mg i.v. for the next 4 days, and then 500 mg i.v. once after 4 weeks. Patients >65 yr old, <60 kg in weight, or in poor nutritional state received FU (500 mg, i.v. push) for 5 days and one repeat dose after 4 weeks. The 5-yr survival rate is calculated for patients with no evidence of disease (NED). In Duke's class C disease, the rate was 24.3% with surgery alone, but was 57.7% ($p<0.01$) when treatment followed surgery. The 5-year NED rate in Duke's class B disease was 58.8% with surgery alone and 81.6% ($p<0.02$) with surgery and FU treatment. The 1-, 2-, and 3-yr survival rates in Duke's class C disease are strikingly different for the experimental and control groups, but the difference in Duke's class B disease was not significant until the 5th yr. FU therapy appears to offer a statistically significant improvement in the 5-yr disease-free survival rates of patients with Duke's class B or C disease when used in a carefully selected and controlled setting.

4018 LEIOMYOMAS OF THE RECTUM AND ANAL CANAL: REPORT OF SIX CASES AND REVIEW OF THE LITERATURE.

(Eng.) Kusminsky, R. E.; Bailey, W. (6064 Village Glen Drive, Apt. 4153, Dallas, Texas 75206). *Dis. Colon Rectum* 20(7):580-599; 1977.

A review is presented of 79 cases of leiomyoma of the rectum and anal canal reported in literature from 1959 to 1975, of which six cases (author's series) are presented in detail. The patient's age and sex, the size and location of the tumor, the symptoms of the lesion and their duration, the preoperative diagnosis, treatment, and follow-up comments are presented in tabular form for the 79 cases. Since 1872, 168 rectal leiomyomas have been reported in the literature, indicating a very low incidence of the disease. The incidence, etiology, location, age and sex incidence, signs and symptoms, diagnosis, pathology, and treatment of the disease are discussed. The incidence of these lesions is greatest between the ages of 40 and 59 yr. Leiomyomas located in the anal canal and sphincter are the rarest (a case report is given; 11 cases total are found in the literature). Most patients have a combination of symptoms among which most frequent are the presence of a palpable mass, bleeding, constipation, and pain. Diagnosis is usually obtained by digital examination of the rectum. Those tumors with an original diameter of 5 cm or more show a stronger tendency to recur and/or become malignant. It is concluded that leiomyomas must be approached with serious consideration of radical treatment, particularly when their largest diameter is 5 cm or more. More adequate follow-up studies of these patients are suggested.

4019 THE PATHOPHYSIOLOGIC BASIS FOR THE ANGIOGRAPHIC SIGNS OF VASCULAR ECTASIAS OF THE COLON.

(Eng.) Boley, S. J.; Sprayregen, S.; Sammartano, R. J.: Adams, A.; Kleinhaus, S. (Montefiore Hosp. and Medical Center, 111 East 210th St., Bronx, NY 10467). *Radiology* 125(3):615-621; 1977.

Forty-five superior mesenteric angiograms from 25 patients with histologically and radiographically diagnosed colonic ectasia were reviewed to determine reliable individual diagnostic signs. Of eight angiographic signs evaluated, four were considered important, reliable, and readily identifiable, independent of observer interpretation: (1) a densely opacified, slowly emptying, dilated, tortuous, intramural cecal vein that remains visualized after other mesenteric veins have emptied (seen in 23 of the 25 patients); (2) a vascular tuft, best visualized in the arterial phase and usually located at the termination of a branch of the ileocolic artery (seen in 17); (3) an early filling vein that visualized within 4-5 sec (seen in 14), usually a local vein in the cecum or right colon or the ileocolic vein; and (4) an intraluminal, localized extravasation of contrast material that usually appeared during the arterial phase and persisted throughout the study (seen in 2). The first three signs were present in 11 of the 25 patients. Eight patients displayed combinations of two signs. Five patients demonstrated only the dense, slowly emptying vein, and one patient had only the early filling vein. In serial angiograms done on three of four patients, the late emptying intramural vein was found months to years before the other signs could be identified; it was the earliest and most frequently observed angiographic sign of ectasia. The vascular tuft was a less frequent sign that developed next on the serial angiograms and appears to represent a more advanced stage of the degenerative process. The early filling vein corresponds to the final stage of the process. Vascular ectasias appear to be degenerative lesions requiring many years to develop, the direct cause of which appears to be repeated, partial, intermittent, low-grade obstruction of the submucosal veins, especially where they pierce the muscle layers of the colon. Dilatation and tortuosity of the submucosal vein and then of the venules of the arteriolar-capillary-venular units draining into it occurs, leading to alterations in the arteries supplying the area and the extramural vein draining it.

4020 HISTOLOGIC STUDIES OF RECTOCOLIC AGANGLIONOSIS AND ALLIED DISEASES.

(Eng.) Munakata, K.; Okabe, I.; Morita, K. (Nihon Univ. Sch. Medicine, Oyaguchi, Itabashi-ku, Tokyo, Japan). *J. Pediatr. Surg.* 13(1):67-75; 1978.

Histologic studies of the rectum and large bowel of newborn children with provisional clinical diagnosis of Hirschsprung's disease were performed using a silver impregnation technique. The state of maturity of the ganglia was defined by studying intestinal specimens obtained at operation for aganglionosis in two fetuses and for disease other than Hirschsprung's in two newborn infants. The normal state of the internal anal sphincter was studied in rectal autopsy specimens from two suckling infants and one newborn, none of whom had defecation problems. In the fetuses and newborn infants, Auerbach's plexus was rhombic in form, and the number of ganglia/plexus was about 50. No ganglion cells were found, and many nonmedullated nerve fibers were present in aganglionic segments. Solitary or clustered ganglia and proliferations of nonmedullated nerve fibers were present in the distal portion of the transitional zone. A small number of ganglia per plexus were found in the proximal part of the transitional zone, and a complete plexus was present in the proximal normal intestine. In children aged 6-9 months, Auerbach's plexus exhibited a network structure up to about 2 mm proximally from the lowest part of the internal anal sphincter, and in the newborn infants up to about 4 mm proximally; nerve fibers branched off from these plexuses and ran towards the internal anal sphincters. In 30 newborn infants diagnosed to have Hirschsprung's disease, double rectal suction biopsies were performed following colostomy or ileostomy; 8 of them had further biopsies at 6-9 months. In 22 cases, many or slight proliferations of acetylcholinesterase nerve fibers were observed; in 8 cases, however, hardly any proliferation was recognized, and small ganglia were present. Detailed histologic examination of the bowel, with silver impregnation, revealed that six of these eight cases were hypoganglionic. In five cases, there was no plexus formation but solitary or clustering ganglia were present. In one patient, there was incomplete formation of the plexus and ganglia were observed. Complete plexus gradually formed in proximal intestine in all six cases; in four cases, the diseased segment was short, involving only the rectum and in two cases, it extended to the middle of the descending colon. Proliferation of acetylcholinesterase nerve fibers was rarely observed in the lamina propria or lamina muscularis mucosae of rectal biopsies in the newborns, but these arose by 6-9 months. Small Meisner's ganglia were present in all newborn rectal biopsies. Immaturity of the ganglia (long type) was recognized in a newborn infant who had aganglionosis in the rectum, normal ganglia in the transverse colon, and scarsely any acetylcholinesterase nerve fibers in the lamina propria or lamina muscularis mucosae. Plexus formation and numbers of ganglia corresponded to controls, but the intramural ganglion cells were small and monopolar from the jejunum to the rectum. Despite intravenous hyperalimentation, the patient died 4 months after birth. A patient with microcolon and aganglionic small bowel had no acetylcholinesterase nerve fibers in a rectal biopsy specimen, although small Meisner's ganglia were present. Histologic examination of intestinal autopsy specimens showed a narrow plexus, diminished numbers of ganglia per plexus, and small ganglia from jejunum to anus. It is suggested that the internal anal sphincter muscle at the dentate line is under the control of Auerbach's plexus and ganglia. Hypoganglionosis can be diagnosed as Hirschsprung's disease from the characteristic findings of acetylcholinesterase nerve fibers in the rectal mucosa, but immaturity of the ganglia and hypogenesis can only be diagnosed by histologic studies that include studies of the form of the intramural plexus, the numbers of ganglia per plexus, and the size of the ganglia.

4021 HISTOCOMPATIBILITY ANTIGENS AND THE ARTHRITIS OF CHRONIC INFLAMMATORY BOWEL DISEASE.

(Eng.) Nicholls, A. (No affiliation given). *Clin. Rheum. Dis.* 3(2):265-280; 1977.

Various types of arthritis associated with ulcerative colitis (UC) and Crohn's disease (CD) are discussed and epidemiological and genetic studies are reviewed to investigate whether other conditions associated with ankylosing spondylitis also have a high frequency of the HLA-B27 antigen. Arthritis associated with chronic inflammatory bowel disease, family associations between chronic inflammatory bowel disease and ankylosing spondylitis, the occurrence of spinal disease in patients and relatives of patients with inflammatory bowel disease, HLA antigens in inflammatory bowel disease and its accompanying arthritis, HLA antigens in the arthritis of inflammatory bowel disease, other genetic markers (blood groups, glucose-6-phosphate dehydrogenase activity, allergic diseases, infective agents), and genetic interpretation are discussed in detail. No definite association has been shown between the distribution of HLA antigens and CD, UC, or the enteropathic arthritis complicating these diseases. HLA-B27 is present in a high proportion of patients with spondylitis complicating inflammatory bowel disease; but not as high as in "idiopathic" ankylosing spondylitis. It is suggested that the presence of B27 in a patient with inflammatory bowel disease confers a greater risk of the development of ankylosing spondylitis than in subjects without bowel disease.

4022 MANAGEMENT OF VOLVULUS OF THE COLON.

(Eng.) Wertkin, M. G.; Aufses, A. H., Jr. (Box 764, Mount Sinai Hosp., Fifth Ave. and 100th St., New York, NY 10029). *Dis. Colon Rectum* 21(1): 40-45; 1978.

The cases of 32 patients with sigmoidal (23), cecal (8), or transverse (1) volvulus of the colon are reviewed and compared with previously reported series in an attempt to define guidelines for the treatment of this entity. In the sigmoidal volvulus group, there were cases of significant neurologic or psychiatric disease (6), cardiovascular disease (7), diabetes mellitus (2), prostatic disease (4), and ulcerative colitis quiescent at the time of volvulus (1). Nonoperative reduction (attempted in 18 patients) was successful with sigmoidoscopy (12), colonoscopy (3), or barium enema (1); it was unsuccessful by sigmoidoscopy in two patients, one of whom died of shock following sigmoid perforation, and there were five recurrences. Fifteen patients underwent 16 operative procedures: 7 emergency treatments (obstructive resection in 5), three-stage resection in 1, detorsion and sigmoidopexy in 1, and 9 elective treatments (sigmoidal resection with primary anastomosis in 8 and obstructive resection in 1). There was one recurrence and one death. In the cecal volvulus group, there were cases of significant cardiovascular disease (2), chronic obstructive pulmonary disease (1), sickle-cell anemia (1), previously diagnosed irritable bowel syndrome (1), previous appendectomy (1), and previous cholecystectomy (1). Nonoperative treatment (attempted in 3 patients) was successful by barium enema (2) and unsuccessful by long intestinal tube (1). Six patients underwent operative procedures, with no deaths and no recurrences. Detorsion (2); detorsion, cecopexy, and cecostomy (2); detorsion and cecopexy (1); and detorsion and cecostomy (1) were performed on an emergency basis, except for one detorsion. Transverse volvulus accompanied by gangrenous bowel was successfully treated operatively. In all cases of sigmoidal volvulus, sigmoidal resection with primary anastomosis after nonoperative reduction is the treatment of choice; obstructive resection is indicated as definitive therapy where operation is mandatory. Appropriate operation appears the treatment of choice for cecal volvulus. The treatment of choice for volvulus of the transverse colon is resection of the redundant segment of colon with end-to-end anastomosis or obstructive resection in the presence of gangrenous bowel or when anastomosis is deemed hazardous.

4023 THE IMMEDIATE RESULTS OF ABDOMINAL PROCTECTOMY WITH DOWNWARD TRANSPOSITION OF THE SIGMOID IN OBESE AND ELDERLY PATIENTS.

LARGE INTESTINE

Ulcerative Colitis

4052 INFLUENCE OF AN ELEMENTAL DIET ON PROTEIN EXUDATION IN CHRONIC INFLAMMATORY BOWEL DISEASE. (Eng.) Axelsson, C. K.; Jarnum, S. (Rigshospitalet, 2100 Copenhagen O, Denmark). *Digestion* 16(1/2):77-86; 1977.

Using ^{131}I-albumin, intestinal protein loss was investigated as a possible indicator of the therapeutic effect of an elemental diet in the treatment of 13 patients with chronic inflammatory bowel disease (9 with ulcerative colitis and 4 with Crohn's disease). Prior prednisone treatment was given in eight cases; in five patients who failed to respond or who responded unsatisfactorily to dietary treatment, prednisone treatment was started or increased after 9-13 days of the dietary treatment. ^{131}I-albumin studies showed no significant change of albumin degradation and, by inference, of intestinal protein loss in the group as a whole. Nevertheless, clinical remission occurred in five patients. A markedly elevated initial albumin breakdown (>16%/day) was associated with poor outlook for the success of treatment. It is concluded that measurement of intestinal protein leakage is of no predictive value as regards the effect of treatment of chronic inflammatory bowel disease with elemental diet. Apparently, diminishing protein exudation is a late phenomenon during a course of clinical remission.

4053 IMMUNOLOGICAL STUDIES IN ULCERATIVE COLITIS. VIII. ANTIBODIES TO COLON ANTIGEN IN PATIENTS WITH ULCERATIVE COLITIS, CROHN'S DISEASE, AND OTHER DISEASES. (Eng.) Carlsson, H. E.; Lagercrantz, R.; Perlmann, P. (Dept. Immunology, Wenner-Gren Inst., Univ. Stockholm, S-106 91 Stockholm, Sweden). *Scand. J. Gastroenterol.* 12(6):707-714; 1977.

The sera of 516 patients with ulcerative colitis, 148 with Crohn's disease, 77 with gastroenteritis, 97 with irritable colon, 12 with salmonellosis, 13 with liver cirrhosis, 16 with urinary tract infection, 158 with other nongastrointestinal diseases, and 158 healthy controls were examined for antibodies to colon antigen. In addition, the reactivity with Common Antigen (CA) of sera from the patients with Crohn's disease, 122 patients with polyposis coli, and 60 relatives of polyposis coli patients was examined. Sera from patients with ulcerative colitis or Crohn's disease had elevated titers to colon antigen from germ-free rats significantly more often ($p<0.05$) than did sera from patients with gastroenteritis, irritable colon, nongastrointestinal diseases, and healthy controls. Elevated anticolon titers in significant frequency were also found in patients with liver cirrhosis, urinary tract infections, and in polyposis coli and their relatives. Women with ulcerative colitis had, on an average, higher titers than men, especially those 30 yr old and over. In Crohn's disease, the antibody titers often increased with time, which was not the case in ulcerative colitis and nongastrointestinal diseases. In conjunction with the results of previous studies, the present study supports the assumption that the antibodies in ulcerative colitis patients react with antigenic determinants distinct from those recognized by the colon antibodies present in other groups, including patients with Crohn's disease and polyposis coli.

PANCREAS

4059 DIAGNOSIS OF PANCREATIC CANCER BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY AND PANCREOZYMIN SECRETIN TEST. (Eng.) Nakano, S.; Takeda, I.; Watashiki, H.; Nakamura, M. (Ogaki Municipal Hosp., 4-86 Minaminokawa-machi, Ogaki City, 503 Japan). *Gastroenterol. Jpn.* 12(4):263-268; 1977.

The cases of 80 patients with pancreatic cancer are reviewed to evaluate the significance and limitations of endoscopic retrograde cholangiopancreatography (ERCP) and the pancreozymin-secretin (PS) test for the precise and detailed diagnosis of the carcinoma of the pancreas. The patients were divided into 10 groups according to the location and size of the tumor. Changes of the common bile duct (CBD), the main pancreatic duct (MPD), and the accessory pancreatic duct (APD) and duodenal loop obtained by percutaneous transhepatic cholangiography (PTC), drip infusion cholangiography (DIC), hypotonic duodenography (HDG), and ERCP were employed for this classification. In cases of pancreatic head cancer in which the tumor is located near the CBD and apart from the MPD, the pancreatogram remained intact or showed slight narrowing with almost normal pancreatic function. The CBD was obstructed either completely or incompletely. Remarkable impairments in the exocrine pancreas and in bile secretion were observed in cases of tumors involving the MPD, APD, and CBD, accompanied by notable changes in the cholangiopancreatogram. However, varying degrees of impairment in the exocrine pancreas and the bile secretion were observed in cases of pancreatic head cancer apart from the MPD, CBD, and APD, depending upon the degree of invasion toward the MPD; neither ERCP nor the PS test were useful for detecting pancreatic cancer that occurred apart from the MPD. ERCP was also useful in the diagnosis of some cases of cancer of the body and tail of the pancreas. Because the results of the PS test can only demonstrate impairments of pancreatic secretory capacity and the results of ERCP delineate only macroscopic changes of the pancreas, a combination of ERCP and the PS test with conventional examinations is suggested for the correct diagnosis of the pancreatic cancer.

4060 TOTAL PANCREATECTOMY FOR CANCER: AN APPRAISAL OF 65 CASES. (Eng.) Ihse, I.; Lilja, P.; Arnesjo, B.; Bengmark, S. (Dept. Surgery, Univ. Lund, Lund, Sweden). *Ann. Surg.* 186(6):675-680; 1977.

Factors influencing operative mortality and morbidity, long-term survival, and metabolic sequelae were reviewed in 65 patients who underwent total pancreatectomy for cancer. The diagnoses were pancreatic cancer in 58 patients, periampullary cancer in 3, cancer of the bile duct in 2, and leiomyosarcoma of the duodenum and cystadenocarcinoma of the pancreas in 1 patient, resp. In 9 of the 58 cases with cancer of the caput, the histological examination revealed multicentricity of the tumor. In 44%, there were signs of degeneration and fibrosis in the distal part of the gland. Patient mortality in the hospital was 23% for the entire series; after 1970, it was 17%, and among patients operated by senior surgeons especially trained in pancreatic surgery, it was 12% during the whole period. The peroperative bilirubin levels seemed to influence survival time. Among 24 patients operated before 1975 in whom the operating surgeon judged the operation as radical, a 5-yr survival of 21% was recorded. In patients without detectable lymph node metastases, the mean survival time was 25 months. The postoperative exocrine insufficiency and diabetes were possible to control. A blood sugar level above 10 μM was found to significantly decrease the frequency of hypoglycemic attacks. Total pancreatectomy appears to be the surgical procedure preferred when radical treatment is selected.

4061 CARCINOMA OF THE PANCREAS AND PERIAMPULLARY REGION: A 41 YEAR EXPERIENCE. (Eng.) Coutsoftides, T.; Macdonald, J.; Shibata, H. R. (Royal Victoria Hosp., 687 Pine Ave. West, Montreal, Quebec H3A 1A1, Canada). *Ann. Surg.* 186(6):730-733; 1977.

A retrospective review of 329 cases of adenocarcinoma of the pancreas and 31 adenocarcinomas of the ampulla and common bile duct seen between 1929 and 1973 was carried out to determine which treatment procedures are most effective. The most common complaints for carcinoma of the pancreas were pain, weight loss, and jaundice in that order of frequency; jaundice was the most common complaint with periampullary lesions. The most common procedure carried out was a gastric and/or biliary bypass. Thirty-five patients underwent pancreatoduodenectomy. The survival of this latter group was longer and better than those undergoing bypass, and in 40% of patients with ampullary carcinoma a cure was effected. Patients undergoing bypass did not live longer than patients undergoing simple exploratory laparotomy. Duration of symptoms and location of tumor within the pancreas (excluding ampullary tumors) did not significantly alter the prognosis. Pancreatoduodenectomy should be undertaken whenever the tumor is deemed resectable, as this provides the only chance for cure and the best palliation.

4062 THE BIOLOGIC ACTIVITIES OF CYSTIC FIBROSIS SERUM. II. ULTRASTRUCTURAL ASPECTS OF THE EFFECT OF CYSTIC FIBROSIS SERA AND CALCIUM IONOPHORE A23187 ON RABBIT TRACHEAL EXPLANTS. (Eng.) Bogart, B. I.; Conod, E. J.; Gaerlan, P. F.; Conover, J. (New York Univ. Medical Center, New York, NY). *Pediatr. Res.* 12(1):15-24; 1978.

The effects of cystic fibrosis (CF) sera and of calcium ionophore A23187 on rabbit tracheal explants were studied ultrastructurally and cytochemically. The sera and calcium ionophore induced a swelling or an increase in the size and possibly the number of secondary lysosomes and an increase in mucus secretion in epithelium of the rabbit tracheal bioassay system. Extended incubation of the rabbit tracheal explants with either CF or control sera produced a cytotoxic effect on the tracheal epithelium, but only after the termination of the normal bioassay time period. Comparative ultrastructural study of the effect of both CF sera and calcium ionophore A23187 on the rabbit tracheal bioassay system indicated that increased membrane permeability to calcium may be important in the production of the ciliary dyskinesia response by CF serum factor(s) in the rabbit tracheal bioassay system.

4063 UNCOMMON PRESENTATION OF PANCREATIC PSEUDOCYST. (Eng.) Chawla, S. K.; Chawla, K.; Sossi, A. J.; LoPresti, P. A. (Queens Hosp. Center, 82-68 164th St., Jamaica, NY 11432). *Am. J. Gastroenterol.* 68(2):154-160; 1977.

Five cases of pancreatic pseudocyst are presented to illustrate a variety of severe and unusual complications of the disease and to afford an early and accurate analysis of the disease. The complications of pancreatic pseudocyst include infection, spontaneous rupture or fistulization, pancreatic ascites, hemorrhage due to erosion of a major vessel, jaundice due to common bile duct obstruction, hypersplenism, pleural effusion, and mediastinal extension of the cyst through the diaphragmatic hiatus. Diagnostic peritoneal aspiration of hemorrhagic fluid, rich with pancreatic enzymes (amylase, 2,055 Somogyi

U; lipase, 17.4 Cherry-Crandell U) confirms the diagnosis of ruptured pseudocyst. Diagnosis of pancreatic ascites requires a high index of suspicion, especially concerning any patient with an elevated serum amylase level and ascites. Elevated levels of ascitic fluid, amylase, lipase, and protein establish the diagnosis of pancreatic ascites. Obstructive jaundice is nearly always associated with clinical and/or laboratory evidence of either acute or chronic pancreatitis. Pancreatic pseudocyst represents an unresolved pancreatic inflammatory process, and can appear in 1 or 2 weeks following an episode of acute pancreatitis; thus, it should be suspected in a patient who is clinically improving but has persistently elevated levels of serum or urinary amylase. The pancreatic pseudocyst, during the process of expansion, may encroach on neighboring structures and even sometimes, incorporate them in the wall of the cyst. The timing of an elective operation for pseudocyst is best dictated by the clinical course of the patient.

PANCREAS

Pancreatitis

4072 EARLY ASSESSMENT OF SEVERITY OF ACUTE PANCREATITIS USING PERITONEAL LAVAGE. (Eng.) Pickford, I. R.; Blackett, R. L.; McMahon, M. J. (General Infirmary, Leeds LS1 3EX, England). *Br. Med. J.* 2(6099):1377-1379; 1977.

The value of peritoneal lavage in determining the severity of acute pancreatitis was assessed in 27 patients. Peritoneal lavage using 1 liter of isotonic saline was performed as soon as possible after diagnosis of acute pancreatitis. There were no complications. Severe attacks (defined retrospectively according to the progress of the attack) were characterized by the presence of free peritoneal fluid and by dark-colored and often opalescent return fluid. The concentrations of albumin, SGOT, and total protein in the return fluid provided good discrimination ($p<0.001$ for each parameter) between severe and mild attacks, and there were also significant differences in the concentrations of amylase, urea, calcium, potassium, bilirubin, alkaline phosphatase, and the WBC count ($p<0.001$, $p<0.01$, $p<0.01$, $p<0.01$, $p<0.01$, $p<0.05$, and $p<0.02$, resp.). Lavage successfully predicted severe disease in five patients whose condition had been clinically assessed as mild.

4073 THE USE OF A NEW PROTEINASE INHIBITOR IN ACUTE PANCREATITIS. (Ger.) Kronberger, L.; Musil, H. E.; Hollerl, G.; Prexl, H. J.; Eide,

M. (Chirurgische Universitatsklinik, Auenbruggerplatz 1, A-8036 Graz, Austria). *Wien. Med. Wochenschr.* 127(16):517-521; 1977.

The therapeutic effectiveness of Pantinol, a new proteinase inhibitor, was studied in 50 patients with acute pancreatitis. Primary acute pancreatitis was diagnosed in 28 patients and postoperative acute pancreatitis in 22. In addition to the conventional therapy, the patients received i.v. infusions of Pantinol in 5% glucose or levulose solution. The daily dose (administered in 2-4 portions) was 400,000-1,500,000 U in patients with acute primary pancreatitis, and 500,000-1,000,000 U in those with postoperative pancreatitis, depending on the grade of the disease. The therapy resulted in the rapid subsidence of the symptoms and normalization of the elevated urinary amylase and leukocyte levels in all but four patients with acute primary pancreatitis. The amylase levels were consistently normal after the 10th day. Pantinol was well tolerated by the patients. The findings indicate the great value of Pantinol in the treatment of patients with acute pancreatitis.

4074 SERUM PARATHYROID HORMONE IN PANCREATITIS: A PROSPECTIVE STUDY OF 40 PATIENTS. (Fre.) Galmiche, J. P.; Mallet, E.; Colin, R.; Reumont, G.; Geffroy, Y. (Hopital Charles-Nicolle, 1, rue de Germont, F 76038 Rouen Cedex, France). *Gastroenterol. Clin. Biol.* 1(8/9):653-659; 1977.

Serum parathyroid hormone (PTH) levels were determined in 40 randomized patients with pancreatitis. Calcifying pancreatitis was diagnosed in 20 patients and noncalcifying pancreatitis in the others. Pancreatitis was the first clinical manifestation of primary hyperparathyroidism, which was recognized by a high PTH level in two patients. In the other 38 patients with pancreatitis and without primary hyperparathyroidism, the mean PTH level was not significantly different from that found in the control group (1.28 ng/ml versus 1.18 ng/ml in the controls). The PTH level found in 4 of the 38 patients exceeded the upper limit of the normal range, but primary hyperparathyroidism was ruled out on the basis of other biochemical findings. The pathogenesis of pancreatitis in hyperparathyroidism has not yet been clarified, but hypercalcemia is believed to play an important role, either by activating the pancreatic trypsinogen, or by facilitating the precipitation of calcium in the pancreas.

4075 INHIBITION OF EXAGGERATED GASTROINTESTINAL GLUCAGON RESPONSES IN CHRONIC PANCREATITIS BY SOMATOSTATIN. (Eng.) Botha, J. L.; Vinik, A. I.; Child, P. T.; Jackson, W. P. U. (Dept. Medicine, Univ. Cape Town, Cape Town, South Africa). *J. Clin. Endocrinol. Metab.* 45(6):1265-1270; 1977.

The effects of somatostatin on cross-reacting gastrointestinal glucagon-like immunoreactivity (GLI) and "pancreatic" immunoreactive glucagon (IRG) responses to p.o. glucose were studied in five patients with chronic pancreatitis and five normal controls. Glucose administration caused an exaggerated release of GLI and a slight early rise in IRG concentration in patients with chronic pancreatitis (who have impaired insulin release). The i.v. administration of somatostatin (200 μg), followed by infusion of an additional 200 μg over 2.5 hr, abolished the GLI and insulin responses, but did not change glucose tolerance. This result contrasts with the relatively minor effects of somatostatin on GLI responses in controls, where the clear deterioration in glucose tolerance may relate to inhibition of insulin release.

4076 THE FREQUENCY OF MACROAMYLASEMIA AND THE DIAGNOSTIC VALUE OF AMYLASE TO CREATININE CLEARANCE RATIO IN PATIENTS WITH ELEVATED SERUM AMYLASE ACTIVITY. (Eng.) Durr, H. K.; Bindrich, D.; Bode, J. C. (Medizinische Klinik der Universitat, D-3550 Marburg/Lahn, W. Germany). *Scand. J. Gastroenterol.* 12(6):701-705; 1977.

The frequency of macroamylasemia was studied in 190 patients with elevated serum amylase levels. The value of the amylase to creatinine clearance ratio (C_{am}/C_{cr} ratio) as a screening test for macroamylasemia was assessed in 183 patients. Macroamylasemia was found in three patients. In these patients, macroamylasemia persisted after the total activity of serum amylase had fallen to nearly normal levels. The C_{am}/C_{cr} ratios were determined 14 times in the three macroamylasemic patients. Only one of the 14 values was clearly less than 1%. C_{am}/C_{cr} ratios above 4% were found in 83 patients. In 56 of them, the diagnosis of acute pancreatitis could not be confirmed. Nineteen of 46 patients with acute pancreatitis had C_{am}/C_{cr} ratios below 4%. C_{am}/C_{cr} ratios below 1% were also found in 48 of 134 patients without macroamylasemia. It is concluded that high and low C_{am}/C_{cr} ratios are not specific for acute pancreatitis and macroamylasemia, resp., and that a normal C_{am}/C_{cr} ratio excludes neither acute pancreatitis nor macroamylasemia.

4077 CALCITONIN IN THE TREATMENT OF ACUTE PANCREATITIS. A MULTI-CENTRE DOUBLE BLIND STUDY [Abstract]. (Eng.) Goebell, H.; Ammann, R.; Akovbiantz, A.; Barth, E.; Hahnloser, P.; Herfarth, C.; *et al.* (Pancreatitis Study Group, Essen, W. Germany). *Ir. J. Med. Sci.* 146(Suppl. 1):36; 1977.

4078 A SINGLE CENTRE DOUBLE BLIND TRIAL OF TRASYLOL THERAPY IN PRIMARY ACUTE PANCREATITIS [Abstract]. (Eng.) Imrie, C. W.; Benjamin, I. S.; Ferguson, J. C.; Thompson, W. O.; McKay, A. J.; Blumgart, L. H. (Royal Infirmary, Glasgow G4 OSF, Scotland). *Ir. J. Med. Sci.* 146 (Suppl. 1):35; 1977.

LIVER AND BILIARY TRACT

4086 SALIVARY ANTIPYRINE KINETICS IN HEPATIC AND RENAL DISEASE AND IN PATIENTS ON ANTICONVULSANT THERAPY. (Eng.) Harman, A. W.; Penhall, R. K.; Priestly, B. G.; Frewin, D. B.; Phillips, P. J.; Clarkson, A. R. (Dept. Human Physiology and Pharmacology, Univ. Adelaide, Adelaide, South Australia 5000, Australia). *Aust. N.Z. J. Med.* 7(4):385-390; 1977.

The effects of liver disease, renal failure, and hepatic microsomal enzyme induction on the elimination kinetics of antipyrine in saliva were examined in 6 patients with chronic liver disease, 5 patients with chronic renal failure, 9 patients receiving anticonvulsant therapy, and 20 healthy controls. Antipyrine (10 mg/kg) was given p.o. to all subjects and assayed in saliva by gas-liquid chromatography. The mean antipyrine half-life from saliva in the epileptic subjects receiving anticonvulsant therapy (6 ± 0.9 hr) was significantly shorter than in the normal volunteers (10.7 ± 0.6 hr). Therapy included phenytoin and phenobarbitone, two drugs known to induce hepatic microsomal enzymes. The five subjects with chronic renal failure exhibited no significant difference in salivary antipyrine half-life (11.7 ± 1.9 hr) compared to the controls, whereas the subjects with chronic liver disease and impaired hepatic function had significantly increased half-life values (42.4 ± 10 hr). The results suggest that differences in the activity of hepatic microsomal enzymes are reflected by changes in salivary antipyrine elimination kinetics. Chronic renal failure appeared to have no effect on the function of these enzymes.

4087 SERUM IMMUNOREACTIVE PROLYL HYDROXYLASE IN LIVER DISEASE. (Eng.) Tuderman, L.; Risteli, J.; Miettinen, T. A.; Kivirikko, K. (Dept. Medical Biochemistry, Univ. Oulu, Kajaanintie 52 A, SF-90220 Oulu 22, Finland). *Eur. J. Clin. Invest.* 7(6):537-541; 1977.

The concentration of serum immunoreactive prolyl hydroxylase (SIRPH) was measured in 30 patients with chronic active hepatitis, 13 with primary biliary cirrhosis, 4 with alcoholic or idiopathic cirrhosis, and 4 with acute hepatitis, and the values were compared with those in 23 controls. Increases in SIRPH were found in all patients with liver diseases, individual values being highest in primary biliary cirrhosis in which about two-thirds of the patients had values more than 2 standard deviations above the mean value in the controls. No correlation was found between SIRPH and other tests of liver function or some routine laboratory tests. SIRPH may reflect some hitherto unknown or unmeasured process in the diseased hepatic cells.

4088 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY (ERC) IN NONAMEBIC LIVER ABSCESSES.

(Eng.) Ascione, A.; Elias, E.; Scott, J.; Sherlock, S. (Ospedale Cardarelli-XX Divisione, Sezione Epatologia, Naples, Italy). *Am. J. Dig. Dis.* 23(1): 39-44; 1978.

Two cases of liver abscesses are reported in which the diagnosis was suggested by a combination of liver scanning, ultrasonography, arteriography, and liver biopsy and then confirmed by endoscopic retrograde cholangiography (ERC), which showed intrahepatic extravasation of contrast material from the biliary tree. A 53-yr-old man with a 1-month history of jaundice, colicky periumbilical pain, malaise, lethargy, vomiting, and diarrhea underwent a technetium-99 colloidal liver scan and gallium-67 scan, and ultrasonography, all of which showed an enlarged liver and suggested space-occupying lesions. The liver biopsy showed intensive centrilobular congestion. Benzyl-penicillin was administered in place of cotrimoxazole following demonstration of anaerobic coccus in the liver biopsy. Endoscopic retrograde cholangiopancreatography (ERCP) showed no gallstones and the diagnosis of liver abscesses was confirmed. At laparotomy, pus was drained from one of two cystic cavities in liver lobes, and many firm nodules were found. The patient recovered quickly and was healthy at 1 yr of follow-up. A 13-yr-old male student was seen with fever, malaise, vomiting, and right upper quadrant pain; he had a 17-month history of pyrexia at monthly intervals associated with vomiting and dark urine. He became jaundiced and a laparotomy was performed that showed a markedly enlarged and inflammed liver with multiple adhesions surrounding the gallbladder. No evidence of cholestasis was found in liver biopsy. Liver technetium scan showed no space-occupying lesions. Despite treatment with gentamicin and ampicillin, the patient remained pyrexial with increasing jaundice and anemia. Radiotechnetium scan and celiac arteriography of the liver showed markedly enlarged liver. Gray-scale ultrasound showed no evidence of lesions in the liver. There was no evidence of tumor. ERCP showed a dilated common bile duct and gross distortion of the intrahepatic biliary tree. During treatment with i.v. metronidazole and p.o. cotrimoxazole, the fever subsided. After 3 months, the patient was well, with normal liver function tests, and ERCP showed that the intrahepatic biliary tree was less disorganized. ERCP is a valuable method in the search for an underlying cause in nonamebic liver abscesses due to its ability to delineate clearly the details of the intrahepatic biliary tree.

4089 EPIDEMIOLOGICAL RELATIONSHIP BETWEEN STEROID HORMONES AND LIVER LESIONS.

(Eng.) Mahboubi, E.; Shubik, P. (Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB 68105). *J. Toxicol. Environ. Health* 3(1/2)207-218; 1977.

The incidence of benign liver cell adenomas in female users of steriod sex hormones (oral contraceptives) is reviewed to determine the possible relationship between these drugs and the occurrence of benign liver tumors, entities once considered rare. Pathologists do not yet agree on the nomenclature of these lesions and commonly use terms such as adenoma, benign hepatoma, hepatic cell adenoma, focal nodular hyperplasia, mixed adenoma, solitary hyperplastic nodules, and hamartoma. Among 137 cases in the literature in the past 3 yr, 60 were discovered by sudden onset of symptoms, 54 by gradual onset, 15 incidentally, and 8 by unknown means. In the absence of tumor registries for these lesions, the authors used personal contact with surgeons, family physicians, and pathologists (by mail or interview) to discover 20 additional cases of liver lesions in women in Nebraska currently using oral contraceptives. Of the 20 cases, 4 were diagnosed as primary malignant liver tumors (hepatocellular adenomas) and the remainder as benign liver tumors. The four patients with hepatocellular carcinoma died at surgery or within 2-3 days thereafter; one patient with ruptured benign adenoma and one with spontaneous rupture of the liver also died. A sudden, severe onset of epigastric pain, shock, and symptoms of internal bleeding occurred in 35% of the patients, a gradual onset of pain and the presence of a palpable mass occurred in 45%, and in 20% the lesions were discovered incidentally during surgery for other causes. In 16 of the 20 cases, a mestranol combination pill had been taken. The period of pill use ranged from 3-79 months (mean, 42.3 months). These tumors occurred over the last 10 yr with incidence rates of 0.052/100,000 population in 1968 and 0.169 in 1975; however, more data must be assembled before meaningful incidence rates can be calculated. Studies of hepatomas published by the American College of Surgeons and published world wide during the last 3 years are cited that demonstrate similar results. It is suggested that more information be assembled to establish incidence rates of these liver lesions to discover the risk for oral contraceptive users, and to ascertain which hormones act independently or in combination with other factors as etiological agents of these entities

4090 PRIMARY SARCOMA OF THE LIVER: REPORT OF A CASE WITH EXCELLENT RESPONSE TO HEPATIC ARTERY LIGATION AND INFUSION CHEMOTHERAPY.

(Eng.) Tanner, A. R.; Bolton, P. M.; Powell, L. W. (Royal Brisbane Hosp., Herston Rd., Brisbane 4029, Australia). *Gastroenterology* 74(1):121-123; 1978.

A case of primary undifferentiated liver sarcoma, successfully treated with hepatic artery ligation and infusion chemotherapy, in a 66-yr-old woman is reported. The presenting symptoms included a tender enlarged liver, persistent pyrexia, weight loss, vomiting, and diarrhea. Preoperatively, the presentation was considered to be that of an abscess with associated severe constitutional symptoms requiring urgent drainage. Neither hepatic scan nor ultrasound clearly distinguished between abscess or neoplasm. Celiac axis angiography performed before hepatic artery ligation demonstrated a solid vascular lesion consistent with a neoplasm. The patient's response to palliative treatment with hepatic artery ligation and chemotherapy with 5-fluorouracil (750 mg, 3 weeks) via the hepatic artery was excellent. This may be the first report of such a response in a sarcoma localized to the liver. This therapy may well be useful in symptomatic patients in whom partial hepatectomy is not feasible.

4091 IMMUNE COMPLEXES AND ABNORMAL LIVER FUNCTION IN HAEMOPHILIA. (Eng.) McVerry, B. A.; Voke, J.; Mohammed, I.; Dormandy, K. M.; Holborow, E. J. (Royal Free Hosp., London NW3 2QG, England). *J. Clin. Pathol.* 30(12):1142-1146; 1977.

Immunological parameters were evaluated in 55 hemophiliacs, 55% of whom had abnormal liver function tests. Abnormal ^{125}I-complement component 1q (^{125}I-Clq)-binding activity was found in the sera of 94% of the 55 patients. Sera from 66% of these patients inhibited macrophage uptake of labeled aggregated human IgG in a competitive radiobioassay. These results suggest that large molecular weight immune complexes are present in these sera. Analysis of the precipitates obtained directly from the sera by the addition of 4% polyethylene glycol showed either a mixture of IgG and IgM or IgM alone. There was poor correlation between the radiobioassay results and the Clq-binding activities in the whole group of 55 patients, suggesting a heterogeneous population of complexes. Nevertheless, a significant correlation (r=0.75) was found between Clq-binding activities and the radiobioassay results in seven patients with antibodies to factor VIII, suggesting a homogeneous population of complexes. There was poor correlation between the level of immune complexes and the amount of replacement therapy that the patient had received in the previous 6 months and between the abnormal liver function test results and the Clq-binding activities and radiobioassay results. Only two patients had clinical evidence of liver disease.

4092 GIANT HEMANGIOMATOSIS OF THE LIVER IN INFANCY. (Eng.) Othersen, H. B.; Watanatittan, S. (Medical Univ. South Carolina, 80 Barre St., Charleston, SC 29401). *Am. Surg.* 44(1):20-25; 1978.

Two case reports of hepatic hemangiomatosis in infancy are presented to clarify the definition of this entity, to review its therapy by corticosteroid administration and hepatic artery ligation, and to compare a successful outcome with an unsuccessful one. A liver scan on a 2-month-old girl with increasing abdominal girth, anemia, and edema of lower extremities showed a markedly enlarged liver with little functioning tissue. Retrograde aortogram revealed extensive neovasculature throughout the liver suggestive of diffuse hemangiomatosis. Prednisolone therapy (30 mg i.v. followed by 15 mg every other day) day) was unsuccessful. During exploratory laparotomy, diffuse involvement of the liver by large, cavernous vascular spaces was found, and the right hepatic artery was ligated. Prednisolone treatment was continued and irradiation (total dose, 350 rads over 8 days) was given, but the signs of disseminated intravascular coagulopathy developed with a platelet count of 30,000. The patient died 12 hr following a second operation, during which the proper hepatic artery and the right branch of the portal vein were ligated. A 2-month-old girl was seen with rapidly progressing abdominal distention and a firm palpable mass. X-ray films showed a large liver, while retrograde aortogram visualized a vascular lesion involving the entire liver. The proper hepatic artery was ligated; at this time, the liver was diffusely enlarged with cavernous vascular spaces. Over a period of 2 months after surgery, the abdominal girth increased 5 cm, and liver scan indicated increase in the filling defects with revascularization of the hemangioma. Prednisone (15 mg p.o.) was given every other day. Over 5 months, the abdominal girth increased 3 cm, then decreased slightly, and stabilized. Differential diagnosis of hemangiomatosis is discussed. It is suggested that, in cases of diagnosed hemangiomatosis of the liver, prednisone should be administered early in large doses (up to 40 mg daily for a few days if the abdomen enlarges rapidly). If there is no response after about 2 weeks, operative ligation of the proper hepatic artery should be performed. Radiotherapy is not recommended.

4093 ULTRASTRUCTURAL OBSERVATIONS ON KUPFFER CELLS IN INTRAHEPATIC CHOLESTATIC JAUNDICE. (Eng.) Djaldetti, M.; Zahav, L. H.; Gafter, U.; Mandel, E. M. (Hasharon Hosp., Petah-Tiqva, Israel). *Arch. Pathol. Lab. Med.* 102(1):49-51; 1978.

Ultrastructural findings in a liver biopsy specimen from a patient with intrahepatic cholestatic jaundice are reported. Marked dilation of the bile capillaries, disappearance of the microvilli, and thickened ectoplasm were observed. The unusual finding was a great increase in the number of Kupffer cells that contained masses of electron-dense material, most probably bile. A second examination of the liver, performed 1 month later when the liver test results had returned to normal, showed only remnants of the Kupffer cells. The Kupffer cells may play a role in the clearance of the blood from the bile pigments.

4094 UNUSUAL OBLITERATIVE DISEASE OF THE HEPATIC VEINS IN AN INFANT. (Eng.) Burkhardt, A.; Kloppel, G. (Institut fur Pathologie der Universitat Hamburg, Martinistr. 52, UKE, D-2000 Hamburg 20, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 375(3):225-232; 1977.

The case of a 3-month-old boy with fatal congenital leukemia treated with cytostatic drugs (cytosine-arabinoside, 185 mg; vincristine, 0.8 mg) who developed hepatic fibrosis with obliterative lesions of the small hepatic veins is presented. The vascular changes were characterized by an unusual, hitherto unreported angiomatoid proliferation of the endothelium. The process is compared with the more common subendothelial fibrous type of "veno-occlusive disease." The etiology may involve a secondary reaction of the endothelium to a cytostatic-induced lesion with hepatic fibrosis.

4095 'PSEUDOCIRRHOSIS' IN HEREDITARY HAEMORRHAGIC TELANGIECTASIA. (Eng.) Cooney, T.; Sweeney, E. C.; Coll, R.; Greally, M. (Sch. Pathology, Trinity Coll., Dublin, Ireland). *J. Clin. Pathol.* 30(12):1134-1141; 1977.

The case of a 68-yr-old woman with hereditary hemorrhagic telangiectasia (HHT) who developed telangiectasia-associated hepatic fibrosis is described. The patient died of oat-cell carcinoma of the lung. In addition to the structural alterations that have been described previously in HHT, the liver exhibited focal midlobular hepatocyte necrosis and tumor metastases. The hepatocyte hyperplasia in this patient may have been related to high-dose estrogen therapy for HHT.

4096 THE MYTHOLOGY OF HEPATIC TRAUMA--OR BABEL REVISITED. (Eng.) Walt, A. J. (Wayne State Univ. Sch. Medicine, 540 East Canfield Ave., Detroit, MI 48201). *Am. J. Surg.* 135(1):12-18; 1978.

Selected aspects of hepatic injury are reviewed on the basis of case reports for 1961-1976 of 1,404 patients with liver injuries who underwent surgery to clarify the surgical problems encountered in this entity and to dispel a number of common but erroneous ideas concerning this subject. The causes of liver injuries were gunshots (55.3%), stabbing (34.2%), and blunt instruments (10.5%). Isolated hepatic injuries were rare (e.g., <10% in patients with blunt injury); mortality was proportional to the number of organs injured, and exceeded 50% when four organs were damaged. The chest, extremities, head, vascular structures, intestines, and spleen (in descending order of frequency) were the sites of associated injuries, which were often multiple. Surgical methods for treatment are quite varied and are tabulated. Hemorrhage was the major cause of death (62.5% of deaths), followed by sepsis and/or respiratory failure (15%), and heart injuries (15%). In just more than 50% of patients, bleeding from the liver had stopped spontaneously before laparotomy. Manual compression, precise ligation of small arteries or veins, and suturing are also able to produce hemostasis when appropriately applied. Hemobilia was observed in only one case. If bleeding was persistent, apparently arterial, and not associated with a smashed lobe requiring resection, hepatic artery ligation merits consideration. The long-standing aversion to this procedure is challenged, showing that hepatic failure is rare and that sepsis is not an inevitable outcome following this procedure. Indications for hepatic artery ligation are given, and alternatives discussed. Resectional debridement can achieve excellent results, microcrystalline collagen applied to a raw surface to aid in hemostasis has not been sufficiently evaluated, true lobectomy has fallen into deserved disrepute except in well-selected instances, and the gauze pack has clearly useful applications. The cannulation of retrohepatic inferior vena cava performed in nine patients was unsuccessful, but it is likely that the type of patient selected for this procedure markedly influences the outcome. A prospective, randomized study of the use of the T-tube for drainage of the common and bile ducts indicates that this procedure should be avoided except in selected cases in which the extrahepatic ducts have themselves been injured. The experience collected here indicates the necessity of critical evaluation of all ideas and procedures in any scientific field.

4097 SELECTIVITY IN THE MANAGEMENT OF HEPATIC TRAUMA. (Eng.) Flint, L. M.; Mays, E. T.; Aaron, W. S.; Fulton, R. L.; Polk, H. C., Jr. (Univ. Louisville Sch. Medicine, Health Sciences Center, Louisville, KY). *Trans. South. Surg. Assoc.* 88:121-126; 1977.

A retrospective review of 178 consecutive patients who sustained hepatic injuries confirmed that selective hepatic artery ligation (SHAL) is an efficient means of definitive hemostasis. Hepatic wounds were managed by drainage, suture, resectional debridement, SHAL, and formal lobectomy, or combinations thereof. As the injury grade increased, SHAL was employed more frequently. Hepatic artery interruption was successful in controlling arterial bleeding from the hepatic parenchyma in all patients in whom it was employed. The operative records of 59 patients undergoing SHAL disclosed that in 82% the decision to employ SHAL followed the failure of conventional modalities to control arterial bleeding. The mortality among 59 patients who underwent SHAL was 31% compared to an overall mortality for all other treatment modalities of 22%; this difference was not statistically significant. The incidence of perihepatic sepsis following hepatic artery interruption was also not significantly increased when compared with other modalities. Overall, the most frequent complications after severe hepatic trauma were bleeding from extrahepatic sites and sepsis, which occurred in 12 and 10 patients, resp.

4098 ARTHROPATHY IN WILSON'S DISEASE. (Fre.) Boudin, G.; Pepin, B.; Hubault, A.; Goldstein, B.; Lidy, C. (Hopital Lariboisiere, 2, rue Ambroise-Pare, F 75475 Paris Cedex 10, France). *Ann. Med. Interne (Paris)* 128(11):853-856; 1977.

Wilson's disease with neurological symptoms and arthropathy was diagnosed in a 30-yr-old man in 1956. D-penicillamine treatment (1-1.5 g/day) was begun in 1960 and continued to the present; it produced considerable regression of the neurological signs after several months, disappearance of Kayser-Fleischer rings after 4 yr of treatment, and complete compensation of the liver status. Gradual progression of the articular symptoms necessitated the insertion of a MacKee prosthesis in the knee in 1968. Investigation of a surgical specimen revealed condensation of the bone surfaces of the joint; para-articular calcification at the points of insertion of the capsula, ligaments and sinews; and a hypervascularized, angiomatous synovial membrane. The physiopathology of arthropathy in Wilson's disease is unknown. There seems to be no correlation between the intensity of the neurologic, hepatic, and renal syndromes and the arthropathy.

4099 ANGIOGRAPHIC STUDY OF THE VASCULARIZATION OF PRIMARY MALIGNANT LIVER TUMORS: HISTOLOGICAL CORRELATION. (Spa.) Pinchuk, L.; Zeilicoff, R.; Falcon, O.; Kesner, L.; Buquet, J.; Figueroa, M.; Cimino, C. (No affiliation given.). *Acta Gastroenterol. Latinoam.* 7(1):23-31; 1977.

4100 BENIGN LIVER TUMORS IN CHILDREN. (Fre.) Djaja, M.; Bumbic, S.; Lazovic, M. (Pediatric Surgery Clinic, Univ. Belgrade, Belgrade, Yugoslavia). *Ann. Chir. Infant.* 18(1):53-58; 1977.

4101 CURRENT ASPECTS OF PRIMARY LIVER CANCER IN ADULTS (PART IV): PATHOLOGIC ANATOMY. (Spa.) Herrerias, J. M.; Velasco, A.; Matilla, A.; Garrido, M. (Hospital Clinico Universitario de Sevilla, Seville, Spain). *Rev. Esp. Enferm. Apar. Dig.* 49(6):789-800; 1977.

4102 CURRENT ASPECTS OF PRIMARY LIVER CANCER (PART V): PROGNOSIS AND TREATMENT. (Spa.) Herrerias Gutierrez, J. M.; Jimenez Saenz, M.; Garrido Peralta, M. (Hospital Clinico Universitario de Sevilla, Sevilla, Spain). *Rev. Esp. Enferm. Apar. Dig.* 50(1):99-108; 1977.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

4116 PHENOBARBITAL IN PROPHYLAXIS OF NEONATAL JAUNDICE: A CONTROL TRIAL OF TWO REGIMENS. (Eng.) Salle, B.; Pasquoer, P.; Desebbe, Cl.; Rouzioux, J. M.; Barouty, B. (Hopital Edouard Herriot, Place d'Arsonval, F-69374 Lyon, France). *Helv. Paediatr. Acta* 32(3):221-226; 1977.

The effect of two different dose schedules of phenobarbital on serum bilirubin in premature and full-term newborn infants was compared to determine the minimal period of drug administration required for the prophylaxis of neonatal jaundice. Single i.m. injections of 10 mg/kg of phenobarbital were given to 155 infants before the 12th hr of life; 111 infants each received an i.m. injection of 10 mg/kg of phenobarbital before the 12th hr of life plus two additional 10 mg/kg p.o. doses on the 2nd and 3rd days of life. Serum bilirubin levels measured between the 2nd and 6th days of life were slightly higher in infants receiving the single i.m. dose of the drug than in infants receiving the three-dose regimen; however, the difference was not statistically significant, except on the 3rd day of life ($p<0.01$). Measurements of the blood phenobarbital level on the 4th day of life showed that the mean blood barbiturate level was significantly lower in infants receiving the single i.m. dose (10.61 ± 5.69 mg/100 ml) than in infants on the multiple-dose regimen (22.51 ± 10.61 mg/100 ml, $p<0.001$). There was no significant relationship between the serum bilirubin peak and the blood barbiturate level on the 4th day. In infants weighing between 1,501 and 2,000 g, for example, the mean serum bilirubin levels on the 4th day of life were 10.02 ± 2.37 mg/100 ml in those who received a single phenobarbital dose and 9.78 ± 4.72 mg/100 ml in those who received three doses of the drug. It is concluded that the single injection has the same effect as the prolonged administration, provided it is given within 12 hr after birth.

4117 OBSTRUCTIVE JAUNDICE DUE TO A CHLORINATED HYDROCARBON IN BREAST MILK. (Eng.) Bagnell, P. C.; Ellenberger, H. A. (Izaak Walton Killam Hosp. Children, P.O. Box 3070, Halifax, Nova Scotia B3J 3G9, Canada). *Can. Med. Assoc. J.* 117(9):1047-1048; 1977.

The case is presented of a 6-week-old breast-fed infant with obstructive jaundice and hepatomegaly due to the presence of the dry-cleaning solvent, tetrachloroethylene, in the mother's milk. When breast feeding was discontinued, rapid clinical and biochemical improvement followed. The child grew normally and had normal liver function during 2 yr of follow-up.

4118 DIAGNOSIS OF FUNCTIONAL GILBERT TYPE HYPERBILIRUBINEMIA IN CHILDREN. (Rus.) Syrieva, T. N.; Spasibko, A. M.; Pisarev, A. G.; Fedotov, V. V. (Dept. Infectious Childhood Diseases, N. I. Pirogov Second Moscow Medical Inst., Moscow, USSR). *Vopr. Okhr. Materin. Det.* 22(2):17-20; 1977.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

4119 ADVERSE DRUG REACTIONS INVOLVING THE LIVER: PROBABLE MECHANISMS. (Eng.) Schaffner, F.; Popper, H. (No affiliation given). *Mt. Sinai J. Med.* 44(6):813-820; 1977.

Metabolic and immune aspects of probable mechanisms of adverse hepatic drug reactions, conventionally separated into predictable and nonpredictable ones, are discussed. The former are dose-dependent, usually have a short latent period, and can be reproduced in animals. The latter are usually dose-independent, have a prolonged latent period, are only exceptionally produced in animals, are rare in children, and occur in only a few of the persons exposed. Drugs influence the cytoskeletal structure of hepatic cells in many ways altering both internal composition and external cell surfaces, which can affect cellular functions. On the other hand, the exposure of some previously hidden membrane proteins or the alteration of membrane proteins by drugs or their metabolites may induce humoral antibody formation, as well as a cell-mediated immune response. The immunologic reaction initiated by drugs and eventually causing hepatocellular injury may develop rapidly within two weeks after drug exposure (e.g., halothane hepatitis) or be delayed and appear slowly after months of therapy (e.g., chronic hepatitis from isoniazid, oxyphenisatin, methyldopa, or even aspirin). Liver injury can be caused by drugs (e.g., polychlorinated biphenyls) acting on cytochromes in the system of drug metabolizing enzymes. Intermediary drug metabolites can also act as toxic or carcinogenic agents. Each drug or metabolite appears to bind preferentially to certain types of macromolecules and probably at specific sites (e.g., binding to DNA initiates carcinogenesis). Toxic intermediates may injure the vascular endothelium leading to veno-occlusive disease (urethane) or the Budd-Chiari syndrome (oral contraceptives). Some drugs (e.g., chloropromazine) and their metabolites probably interfere directly with bile secretion, causing cholestasis. The multiplicity of drug effects makes prevention of adverse drug reactions in the liver extremely difficult. Thus, newer pharmacological and immunological observations confirm the accepted classification of adverse hepatic reactions as (1) predictable toxicities, (2) nonpredictable hepatic reactions, and (3) nonpredictable cholestatic reactions and reveal that they have definable mechanisms. These three reactions may be combined in variable proportions in individual cases, and one drug may elicit different mechanisms, but one reaction will predominate with each drug at one time point in a case.

4120 APRINDINE-INDUCED LIVER INJURY. (Eng.) Elewaut, A.; Van Durme, J. P.; Goethals, L.; Kauffman, J. M.; Mussche, M.; Elinck, W.; *et al.* (Akademisch Ziekenhuis, De Pintelaan 135, B-9000, Gent, Belgium). *Acta Gastroenterol. Belg.* 40(5/6): 236-243; 1977.

Five cases of hepatotoxicity due to the administration of the antidysrhythmic agent aprindine (100 mg/day) are reported. In all five patients, the adverse reaction appeared after a rather brief latent period (1-6 weeks). There were no other manifestations of hypersensitivity such as fever, rash, arthralgia, or eosinophilia. There were few constitutional symptoms, but in two patients severe cholestatic jaundice appeared within 2-3 weeks after initiation of the drug. After withdrawal of the drug, jaundice persisted for many weeks, but the patients recovered completely. There additional patients presented a moderate form of hepatitis, with concomitant elevations of serum amylase and lipase levels in two of them, suggesting a concomitant toxic pancreatitis. Readministration of aprindine for 3 days to these three patients was soon followed by a marked increase in the levels of serum transaminases, thus confirming the offending role of aprindine. It is suggested that the toxicity of aprindine is probably based on an idiosyncrasy of the patient.

4121 HEPATIC TOXICITY ASSOCIATED WITH GOLD THERAPY. (Eng.) Favreau, M.; Tannenbaum, H.; Lough, J. (Montreal General Hosp., Rm. 602 L.H., 1650 Cedar Ave., Montreal, Quebec H3G 1A4, Canada). *Ann. Intern. Med.* 87(6):717-719; 1977.

The clinical, biochemical, and histologic features of three patients who developed cholestatic jaundice after the initiation of chrysotherapy for rheumatoid arthritis are described. Gold sodium thiomalate had been administered in dosages of 37.5, 60, and 110 mg before the onset of jaundice. Liver function studies indicated a cholestatic jaundice in all subjects. One patient underwent exploratory laparotomy because of progressive jaundice. Liver biopsy was done in two patients. In one patient, significant bile stasis and thrombi were seen in the biliary tree. In another patient, liver biopsy showed ballooning of hepatocytes with minimal cholestasis. All patients recovered spontaneously. Awareness of this rare complication may prevent unnecessary diagnostic and surgical procedures in patients with rheumatoid arthritis who may develop jaundice while receiving chrysotherapy.

4122 HALOPERIDOL-INDUCED LIVER DISEASE. (Eng.) Fuller, C. M.; Yassinger, S.; Donlon, P.; Imperato, T. J.; Ruebner, B. (Univ. California, Davis, Sch. Medicine, Davis, CA). *West. J. Med.* 127(6):515-518; 1977.

The cases of two schizophrenic women in whom liver dysfunction developed during therapy with haloperidol are described. The dosages used were within the range recommended for severely disturbed psychiatric patients (40 mg/day in the first patient, 20-25 mg/day in the second). In the first patient, a generalized hypersensitivity reaction developed; the other patient presented with painless jaundice. Biochemically, both patients showed evidence of mild hepatocellular disease and cholestasis. In neither patient was evidence of extrahepatic biliary obstruction found. Liver biopsy in the first patient showed evidence of a hypersensitivity reaction, with some hepatocellular necrosis, but predominant cholestasis. In the second patient, only cholestasis was seen. Haloperidol is felt to be etiologically related to the liver disease seen in these two patients.

4123 SPECTRUM OF METHYLDOPA LIVER INJURY. (Eng.) Thomas, E.; Rosenthal, W. S.; Zapiach, L.; Micci, D. (New York Medical Coll., 1249 Fifth Ave., New York, NY 10029). *Am. J. Gastroenterol.* 68(2):125-133; 1977.

The occurrence of liver injury in seven patients receiving alpha methyldopa for hypertension is reported. All patients presented with symptoms indistinguishable from viral hepatitis, including jaundice and liver enlargement. Histological changes ranged from those consistent with acute hepatitis to those of chronic active hepatitis and subacute hepatic necrosis. On biopsy, the liver of one patient with subacute hepatic necrosis showed severe centrilobular and midzonal injury with a marked inflammatory response consisting of immunocytes, multinucleated cells, rosette formation, and the edge of an area of collapse. This patient, despite corticosteroid administration and supportive measures, rapidly progressed to hepatic failure and died. The autopsy revealed postnecrotic cirrhosis. The architecture of the liver at autopsy was disrupted by extensive fibrosis with nodule formation. There was also marked ductular regeneration. The parenchyma demonstrated both fine and large droplet fatty infiltration, continued liver cell injury, and some bizarre-looking parenchymal cells. Bile extravasates were visible within the fibrous scar. Inadvertent rechallenge with alpha methyldopa after recovery resulted in a dramatic recurrence of symptoms in one patient, indicating that some type of hypersensitivity phenomenon is involved. This finding is supported by the development of autoimmune phenomena, which were observed in two of the patients.

4124 FULMINANT HEPATITIS IN PATIENTS TREATED WITH ISONIAZID AND RIFAMYCIN. A POSSIBLE CONSEQUENCE OF ISONIAZID HEPATOTOXICITY ENHANCED BY ENZYME INDUCTION [Abstract]. (Fre.) Pessayre, D.; Degott, C.; Nouel, O.; Migeut, J. P.; Rueff, B.; Benhamou, J. P. (INSERM, Hopital Beaujon, Clichy, France). *Gastroenterol. Clin. Biol.* 1(5):489; 1977.

4125 OBTUSE LIVER TRAUMA: OPERATED AND NON-OPERATED PATIENTS WITH HEPATIC INJURY. 16 YEARS EXPERIENCE. (Ger.) Hoffmann, R.; Oesch, I.; Muller, H. P.; Nothiger, F. (Kantonsspital, CH-5001 Aarau, Switzerland). *Helv. Chir. Acta* 44(1/2):93-96; 1977.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

4126 LIVER DYSFUNCTION IN PATIENTS WITH HEMOPHILIA. (Eng.) Hilgartner, M. W.; Giardina, P. (New York Hosp.-Cornell Medical Center, 525 East 68th St., New York, NY 10021). *Scand. J. Haematol.* Suppl. 30:6-10; 1977.

The incidence of post-transfusion hepatitis and liver dysfunction was determined in patients with classical hemophilia who received episodic and/or prophylactic factor VIII concentrate. Of 54 patients, 42.5% had persistent biochemical evidence of liver dysfunction with elevated SGOT and SGPT; 3.8% have persistent hepatitis B surface (HBs) antigenicity and 90% have antibodies to hepatitis B surface antigen (HBsAg). The results were the same for those who were treated episodically and received an average of 153 U of factor VIII weekly as for those treated prophylactically who received an average of 686 U factor VIII weekly. The incidence of clinical and/or subclinical disease is unaffected by the transfusion regimen or the amount of concentrate used. The necessity for close follow-up is emphasized for the determination of chronic liver disease and its further therapy.

4127 VIRAL HEPATITIS: ENZYME ASSAYS AND SEROLOGIC PROCEDURES IN THE STUDY OF AN EPIDEMIC. (Eng.) Rakela, J.; Nugent, E.; Mosley, J. W. (Univ. Southern California Sch. Medicine, 2826 South Hope St., Los Angeles, CA 90007). *Am. J. Epidemiol.* 106(6):493-501; 1977.

An epidemic of viral hepatitis in a residence for multiply handicapped children, recognized very early in its course, was investigated prospectively to permit comparison of enzymatic and serologic tests. Thirty-three residents of the institution and 46 full- and part-time employees were studied by the immune adherence hemagglutination procedure for antibody (anti-HAV) to hepatitis A virus (HAV). Of these, 31 residents and 37 staff members were susceptible at the beginning of the epidemic. Nineteen and six, resp., had anti-HAV seroconversion, indicating HAV infection. Thus, 12 children and 31 staff members of presumed susceptibles did not have serologic evidence of infection. The subclinical/clinical ratio for the children was 1.1:1; for personnel, it was 1:1. Serum alanine aminotransferase (ALT) levels compatible with viral hepatitis occurred in 21 persons who had anti-HAV seroconversion; conversely, there were 10 persons who had ALT abnormality without detectable anti-HAV in late specimens among the total of 68 susceptibles. There was no evidence the latter could be attributed to hepatitis B virus infection; therefore, they may represent the endemic occurrence of non-A, non-B agent(s).

4128 HEPATITIS TYPE B: EPIDEMIOLOGY OF NON-PARENTERAL INFECTION. (Eng.) Pal, S. R.; Clements, C.; Ayyagari, A.; Datta, D. V.; Choudhury, S.; Chhuttani, P. N. (Postgraduate Inst. Medical Education and Res., Chandigarh-160012, India). *Bull. Postgrad. Inst. Med. Education Res. Chandigarh* 11(1):35-42; 1977.

The observation of a monthly variation of the proportion of hepatitis B surface antigen (HBsAg)-positive cases of acute hepatitis in and around Chandigarh, northern India, was investigated by studying the correlation between hepatitis cases and average rainfall, maximum temperature, mosquito density, and the frequency of gastroenteritis. A high proportion of positive cases was noticed in the months of July (13.4%), August (19.5%), and September (18.3%). No significant correlation was found between the proportion of positive cases in the disease month and the mosquito density, rainfall, or temperature at the supposed month of hepatitis B infection. A direct linear relationship was established between the proportion of HBsAg-positive hepatitis cases during the month in which the symptoms occurred and that of gastroenteritis in the supposed month of infection (i.e., assuming a 3-month incubation period).

4129 A LONGITUDINAL STUDY ON THE OCCURRENCE OF AUTOANTIBODIES IN THE COURSE OF ACUTE HEPATITIS B. (Eng.) Niermeijer, P.; Gips, C. H.; Verkerk, S.; Snijder, J. A. M. (Majella Hosp., Bussum, Netherlands). *Acta Hepatogastroenterol.* 24(5): 326-333; 1977.

The incidence, titers, and fluorescence patterns of auto-antibodies were studied in a prospective, longitudinal study of 38 patients with acute hepatitis B (AHB) to correlate the results with clinical and biochemical findings in these patients. Five patients were followed for 6-25 weeks after the maximal SGPT level was observed, while 33 were followed for 4-7 yr. Antibodies to nuclei, bile canaliculi, mitochondria, microsomes, or parietal cells were not detected in any of the 354 serum samples. Smooth muscle antibody (SMA) was present in 117 samples from 23 patients, disappeared (1-14 weeks after first detection) from the sera of the patients that subsequently recovered, remained present for at least 4 yr in the one patient with persistent hepatitis B surface antigenemia, and, when present, was always positive at the time of the SGPT peak. Maximal SMA titers were 1:10 (11 patients), 1:50 (9), 1:200 (2), and 1:400 (1). SMA titers higher than 1:50 began from -2 to +3 weeks and ended from 0 to 5 weeks after the SGPT peak. The sera of 6 patients exhibited fluorescence in smooth muscle cells only; in 17 others, fluorescence was also seen around renal tubules, in glomeruli, in hepatocytes, and in gastric mucosa in varying combinations. The type of fluorescence pattern did not correlate with titer height. There was no correlation between the presence of SMA and age, sex, extrahepatic symptoms, height of peak values for SGPT, bilirubin level, alkaline phosphatase level, or ESR. Patients with SMA $\geq$1:50 had their gammaglobulin peak nearly simultaneously with the SGPT peak ($p=0.02$), and their thymol turbidity (TT) peak was 25 U or higher, whereas 9/10 patients with SMA titer of 1:10 and the 9 patients who were SMA-negative had a TT peak <25 U ($p<0.0001$). Sera from one patient whose SMA was 1:10 produced a coarse granular fluorescence in the proximal renal tubules 1 and 2 weeks after the SGPT peak. This autoantibody assessment adds new features to the clinical and biochemical picture of the "median patient" with AHB.

4130 HEPATITIS B SURFACE ANTIGEN (HBsAg) AND ANTIBODY TO HBsAg: PREVALENCE IN HOMOSEXUAL AND HETEROSEXUAL MEN. (Eng.) Dietzman, D. E.; Harnisch, J. P.; Ray, C. G.; Alexander, E. R.; Holmes, K. K. (Dept. Pediatrics, Univ. Washington, Seattle, WA 93114). *JAMA* 238(24):2625-2626; 1977.

The prevalence of serum hepatitis B surface antigen (HBsAg) and antibody to HBsAg (anti-HBs) was compared in 144 homosexual men, 111 heterosexual men with urethritis, and 111 healthy men not questioned about their sexual behavior. HBsAg and anti-HBs were present in 5.6% and 34%, resp., of the homosexual men. The prevalence rates were only 0.9% and 3.6%, resp., in the heterosexuals with nongonococcal urethritis, and also 0.9% and 3.6% in the healthy men. Thus, previous exposure to hepatitis B virus (HBV) was estimated to be 8.8 times greater for homosexual men than for heterosexual men. All four HBsAg-positive sera from homosexual men were subtyped as "*ad*," whereas subtype "*ay*" is preponderant in i.v. drug abusers. Future public health measures to control HBV infection should address the prevention of sexually transmitted HBV infection among homosexual men.

4131 SEROEPIDEMIOLOGICAL INVESTIGATION OF PATIENTS AND FAMILY CONTACTS IN AN EPIDEMIC OF HEPATITIS A. (Eng.) Frosner, G. G.; Overby, L. R.; Flehmig, B.; Gerth, H. J.; Haas, H.; Decker, R. H.; *et al.* (Max v. Pettenkofer-Institut fur Hygiene und Medizinische Mikrobiologie, Pettenkoferstr. 9a, 8000 Munchen 2, W. Germany). *J. Med. Virol.* 1(3): 163-173; 1977.

Serial blood and fecal samples were collected from a total of 53 patients and family contacts during an outbreak of hepatitis A in a village of 6,361 inhabitants. The samples were tested by a solid-phase competitive type radioimmunoassay for hepatitis A antigen and hepatitis A antibody. The amount and duration of excretion of hepatitis A antigen was correlated with the severity of the illness. In two severe clinical cases, hepatitis A antigen was demonstrated in fecal extracts 11 days before the onset of jaundice and continuing for 10 days thereafter, with maximum shedding during the late incubation period. Fecal antigen was demonstrated in low concentrations for only 2 days in a patient with mild disease and in a person with subclinical infection. There was an inverse correlation between the incidence of infection and prevalence of hepatitis A antibody and age. Of 24 infections, 19 occurred in persons in the age group 0 to 20 yr, a group in which only 6% of individuals had pre-existing antibody. Hepatitis A antibody was present in the serum of three persons in low titers of 1:20 to 1:40 on the day jaundice developed. The antibody titers increased very rapidly during the following 2 weeks of illness and slowly during the following months, reaching titers of 1:900 to 1:3,500. In a separate study, a mean antibody titer of 1:591 was found in 13 patients, 12 yr after clinical hepatitis A with jaundice.

4132 DETECTION OF HEPATITIS A ANTIGEN BY IMMUNOFLUORESCENCE. (Eng.) Mathiesen, L. R.; Feinstone, S. M.; Purcell, R. H.; Wagner, J. A. (Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD 20014). *Infect. Immun.* 18(2):524-530; 1977.

Hepatitis A antigen (HAAg) was demonstrated by immunofluorescence (IF) in liver biopsies from chimpanzees with experimental hepatitis A virus infection. Blocking experiments with paired sera from patients with hepatitis types A, B, or non-A, non-B, as well as with purified HAAg, showed that the fluorescence was specific for HAAg. HAAg was demonstrated only in biopsies from chimpanzees inoculated with hepatitis A virus. In two of four chimpanzees biopsied weekly (from before experimental inoculation through convalescence), HAAg was detected by IF before stool shedding of HAAg, elevation in SGPT, or histopathological evidence of liver disease was seen. The HAAg was detected for 4-5 weeks; the last IF-positive biopsy was obtained after SGPT activity had returned to normal. In the two other chimpanzees, HAAg was detected only in the biopsy taken at the time of SGPT elevation. In the early IF-positive biopsies, HAAg was diffusely distributed in the cytoplasm of many cells, but it later accumulated in a focal distribution in the cytoplasm of a few of the hepatocytes and Kupffer cells. This cytoplasmic distribution agrees with previous electron microscopic data.

4133 HEPATITIS A-VIRUS PARTICLES IN STOOLS OF PATIENTS FROM A NATURAL HEPATITIS OUTBREAK IN GERMANY. (Eng.) Flehmig, B.; Frank, H.; Frosner, G. G.; Gerth, H. J. (Hygiene-Institut, Universitat Tubingen, 7400 Tubingen, W. Germany). *Med. Microbiol. Immunol.* 163(3):209-214; 1977.

During a hepatitis outbreak in Southern Germany, 27-nm particles were visualized by immune electron microscopy in the stools of two patients. These particles were serologically similar to hepatitis A virus particles identified in the United States. The buoyant density of these particles was 1.34 g/cm^3 as determined by cesium chloride density centrifugation. The particles were first observed in small numbers in a stool obtained 11 days, and in large numbers in stools obtained 6 and 7 days before the onset of jaundice. Few particles were seen on the day of the onset of jaundice and none thereafter. In both patients, a sereoconversion to hepatitis A virus was demonstrated by immune electron microscopy.

4134 OCCURRENCE OF e ANTIGEN IN ACUTE HEPATITIS B. (Eng.) Gibson, P. E.; Ruparelia, K. (Central Public Health Lab., Colindale Ave., London NW9 5HT, England). *J. Clin. Pathol.* 30(10):925-927; 1977.

The occurrence of e antigen in 44 patients with acute hepatitis B was studied to determine if e was related to the outcome of the illness. In 13.6% of cases, e was detected, and in none of these did the carrier state develop. The hepatitis B surface antigen carrier state developed in 4.6% of the patients and in none of these was e antigen detected. Anti-e was detected in only three cases. Only in the very early acute phase of illness e was detected, and the time that serum samples were taken for the detection of e was considered to be very significant. The occurrence of e was not found to affect the duration of HBs antigenemia in those patients who recovered completely. There was no evidence to indicate that the presence of e indicates an increased risk of chronic liver disease.

4135 RUBELLA ANTIBODIES AND ACUTE VIRAL HEPATITIS. (Eng.) Sloth, K.; Vaheri, A.; Laitinen, O.; Faber, V.; *et al.* (Statens Seruminstitut, Amager Blvd. 80, DK-2300 Copenhagen S, Denmark). *Scand J. Infect. Dis.* 9(3):161-165; 1977.

The frequency of the association between high antibody titers against rubella and measles viruses and acute hepatitis was evaluated in 97 hepatitis patients and in 97 age- and sex-matched controls. Hemagglutination inhibition (HI) and complement fixation (CF) antibodies to rubella, measles, and influenza A viruses were determined in all subjects. In patients, particularly in those over 30 yr of age, a small but statistically significant increase in rubella HI titers was seen. In three hepatitis cases, the rubella HI titers were very high (≥2,560). The antibody levels against measles and influenza A viruses did not differ from those in the controls. The data indicate that a small proportion of acute hepatitis patients show a transient strong humoral immune response to rubella virus.

4136 INDIVIDUAL FREE FATTY ACIDS IN PATIENTS WITH LIVER DISEASE. (Eng.) Gunnlaugsson, O.; Berkowitz, D. (St. Joseph's Hosp., Reykjavik, Iceland). *Am. J. Dig. Dis.* 22(11):1005-1009; 1977.

The total free fatty acids, blood glucose, and individual free fatty acids were studied in 8 patients with viral hepatitis and 13 with cirrhosis. The results were compared with those obtained in nine normal controls. Free fatty acids were significantly elevated ($p<0.05$) in the patients with liver disease as compared with normal controls. A fall in free fatty acids following the ingestion of amino acids and dextrose was noted in normal subjects as well as liver patients. The glucose tolerance test was abnormal in five of seven patients with hepatitis and in four of six with cirrhosis but in none of the controls. Highly significant ($p<0.01$) differences were found in the composition of individual free fatty acids in patients with liver disease as compared with normal subjects; arachidonic and linoleic acids were decreased, while monounsaturated and saturated fatty acids were increased in patients with viral hepatitis and cirrhosis. No significant changes were noted in the percentage composition of individual free fatty acids following the ingestion of amino acids and dextrose.

LIVER AND BILIARY TRACT

Chronic Hepatitis

4143 ACTIVE CHRONIC HEPATITIS: PART 2. (Eng.) Fulton, T.; McCann, V. J. (Royal Perth Hosp., Perth, Western Australia, Australia). *Ulster Med. J.* 45(2):195-204; 1976.

To test the effectiveness of corticosteroid therapy in hepatitis B surface antigen (HBsAG)-negative chronic active hepatitis, 40 patients were treated and observed for 4 months to 13 yr. An initial daily dose of 40-45 mg prednisolone (range, 20-90 mg), gradually reduced to a maintenance dose of 2.5-20 mg/day, was given to 15 patients. Twenty-two patients were given corticotropin (40 U/day, i.m.), which was slowly reduced to an average maintenance dose of 30 U twice weekly. Three patients were given betamethasone. A complete remission was experienced by 17 patients in an average time of 19 months. Nine patients maintained slightly elevated ESR, γ-globulin, transaminase, and alkaline phosphatase levels. Six patients showed good clinical response with only marginal improvement of abnormal liver tests. The remaining eight patients were considered "treatment failures." Twenty-five patients experienced complications of treatment. In seven patients, the complications were considered to be serious; three patients on corticotropin experienced transient hyperglycemia, and two patients had worsening of pre-existing diabetes. One patient on prednisolone experienced persistent hyperglycemia, and one experienced transient hyperglycemia. During the follow-up period, ranging from 4 months to 13 years, 26 patients underwent 58 relapses, 44 of which were hepatic in type. Six of the relapses were characteristic of systemic lupus erythematosus episodes. Twelve of the 40 patients have died. Corticotropin and corticosteroid treatment appear to produce a marked symptomatic improvement with a positive clinical and biochemical picture when the treatment is life-long. The side-effects, more numerous with corticosteroids, are out-weighed by the possibility of developing cirrhosis.

4144 EVIDENCE FOR PHASIC SEQUENCES IN NUCLEAR HBcAg FORMATION AND CELL MEMBRANE-DIRECTED FLOW OF CORE PARTICLES IN CHRONIC HEPATITIS B. (Eng.) Gudat, F.; Bianchi, L. (Dept. Pathology, Univ. Basel, CH-4056 Basel, Switzerland). *Gastroenterology* 73(5):1194-1197; 1977.

Liver biopsy specimens from six patients with chronic aggressive hepatitis B and from one kidney transplant recipient with chronic persistent hepatitis B were examined to study distribution patterns of hepatitis B core antigen (HBcAg). Differential distribution patterns of HBcAg (with gradual transitions) were seen: pure nuclear, mixed nuclear/cytoplasmic, and pure cytoplasmic (diffuse and/or submembraneous). This distribution was combined with spotty expression of hepatitis B surface antigen (HBsAg) in the cytoplasm and liver cell membrane and with Dane particles (DP) in blood. A phasic nuclear formation and release of cores from the nucleus and of DP from the cell, resp., is suggested. Electron microscopy of one biopsy indicates a secretory disturbance as a possible cause for HBcAg accumulation in liver cells, the tolerance of which is attributed to immunosuppression therapeutically induced in four patients and suspected in three (2 dialysis patients, 1 with spontaneous chronic aggressive hepatitis B).

4145 CHRONIC HEPATITIS IN HEMOPHILIA. (Eng.) Hasiba, U.; Spero, J. A.; Lewis, J. H. (Central Blood Bank Pittsburgh, 812 Fifth Ave., Pittsburgh, PA 15219). *Scand. J. Haematol.* (Suppl. 30):27-32; 1977.

The relationship of chronic hepatitis B and/or liver dysfunction to treatment in 113 hemophiliacs was evaluated by determining SGOT and SGPT, and by the presence of circulating hepatitis B surface antigen (HBsAg) or antibody (anti-Hbs). The hemophiliacs were divided into three groups according to treatment pattern. Individuals who had received multiple doses of plasma fractions, derived from four or more commercial lots were placed in group I; group II had been treated with fractions from three or fewer lots; and group III had never received commercial fractions, but had been treated with cryoprecipitate. Abnormal liver function tests (LFTs) were found in 87% of group I and 76% of group II, but in only 16% of group III. Differences in LFTs were minor between treated factor VIII- and IX-deficient patients. All patients treated with 100,000 U or more showed either persistent or intermittent abnormalities. In group I, the history of past, overt hepatitis had no influence on observed LFTs. The sera of all patients in the high exposure and all but one in the low exposure groups were positive for HBsAg or anti-Hbs by radioimmunoassay. Splenomegaly was found in 13% of fraction-treated patients. It is concluded that there is biochemical evidence of liver disease following large exposure to commercial factor VIII or IX fractions, which should temper the physician's decision to start treatment with these fractions. On the other hand, evidence that their continued use produces mounting liver dysfunction is insufficient to withdraw this very effective and life-changing treatment from these individuals.

4146 RAPID PROGRESSION OF CHRONIC ACTIVE TYPE B HEPATITIS IN A PATIENT WITH HYPOGAMMAGLOBULINEMIA. (Eng.) Tong, M. J.; Nies, K. M.; Redeker, M. D. (Los Amigos Hosp., Building 1100, Room 53, 7601 E. Imperial Highway, Downey, CA 90242). *Gastroenterology* 73(6):1418-1421; 1977.

The case of a 19-yr-old man with hypogammaglobulinemia in whom acute hepatitis B rapidly progressed to chronic active liver disease and cirrhosis is described. Absent circulating IgA, significantly low IgG, and normal IgM levels were detected during the acute phase of illness. Enumeration of peripheral lymphocytes revealed a decreased number of T cells and normal numbers of B cells. *In vitro* pokeweed stimulation of immunoglobulin synthesis correlated with the *in vivo* circulating levels of the three immunoglobulins. Cell-mediated immune responses were normal except for lymphocyte stimulation to hepatitis B surface antigen. It is concluded that the defective synthesis of IgG and IgA antibodies to hepatitis B surface antigen contributed to the accelerated progression to chronic active type B hepatitis in this patient.

4147 ON THE PATHOGENESIS OF EARLY RENAL IMPAIRMENT IN CHRONIC ACTIVE LIVER DISEASES (CALD) [Abstract]. (Eng.) Gentilini, P.; Laffi, G.; Buzzelli, G.; Stefani, P.; Masi, R. (III. Dept. Medical Pathology, Univ. Florence, Florence, Italy). *Digestion* 16(4):348-349; 1977.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

4148 GIANT MITOCHONDRIA IN HEPATOCYTES: A DIAGNOSTIC HINT FOR ALCOHOLIC LIVER DISEASE. (Eng.) Bruguera, M.; Bertran, A.; Bombi, J. A.; Rodes, J. (Hospital Clinico y Provincial, Barcelona, Spain). *Gastroenterology* 73(6):1383-1387; 1977.

One hundred and sixty-five coded liver biopsy specimens from chronic alcoholics and specimens from nondrinkers or subjects with low alcoholic intake were studied by light microscopy to evaluate the occurrence and diagnostic significance of giant mitochondria, which have been identified as PAS-negative globular hyalin cytoplasmic inclusions of regular outline, clearly distinguishable from Mallory bodies. In four cases, electron microscopy confirmed that these globules were in fact enlarged mitochondria. The incidence of giant mitochondria was significantly higher in patients with high alcohol consumption (72%) than in those with low or no alcohol intake (10%). Their presence was related to the amount of daily ethanol consumption and to the shortness of abstinence before the biopsy. It was independent of other changes in the liver, and was detected with similar frequency in biopsies showing different alcoholic liver diseases. This study emphasizes that giant mitochondria may be detected by light microscopy in a high proportion of alcoholics, and rarely in nonalcoholic liver diseases. Although less specific, they are much more frequent than Mallory bodies. Consequently, they should be considered as a diagnostic hint of recent and heavy alcoholism.

4149 ASYMPTOMATIC LIVER DISEASE IN ALCOHOLICS.

(Eng.) Bruguera, M.; Bordas, J. M.; Rodes, J. (Hospital Clinico y Provincial, Barcelona, Spain). *Arch. Pathol. Lab. Med.* 101(12):644-647; 1977.

The incidence and nature of liver damage were examined in 154 consecutive asymptomatic chronic alcoholics, and the value of clinical and biochemical examination for predicting the presence of liver disease was assessed. Several types of histologic changes of the liver (cirrhosis, hepatitis, fatty change, hemosiderosis, portal fibrosis) were found in 116 of the alcoholics. No relation was found between the nature of the hepatic damage and either the duration of alcoholism or the presence or degree of clinical and biochemical disturbances. The results of clinical and biochemical examination (presence or absence of hepatomegaly, presence of one or more biochemical abnormalities) of 55 patients with histologic abnormalities were normal, and these patients were considered as apparently healthy alcoholics. Liver biopsy specimens from 61 of 69 asymptomatic alcoholics, who had abnormalities on clinical and/or biochemical investigation, showed hepatic damage under light microscopy, but specimens from the other eight were histologically normal. Conventional liver function tests have limited value in detecting the existence and severity of liver injury, while liver biopsy specimens may reveal a large range of abnormalities in asymptomatic alcoholics.

4150 MEASUREMENT OF ALCOHOL-RELATED EFFECTS IN MAN: CHRONIC EFFECTS IN RELATION TO LEVELS OF ALCOHOL CONSUMPTION. PART A.

(Eng.) Turner, T. B.; Mezey, E.; Kimball, A. W. (Johns Hopkins Medical Inst., Baltimore, MD). *Johns Hopkins Med. J.* 141(5):235-248; 1977.

Information concerning intake-effect relations between alcohol intake and chronic dysfunctions of the liver, pancreas, cardiovascular system, testis, and fetus are reviewed. Alcohol and the elderly, evidence of favorable effects of alcohol, and the question of alcoholism are also discussed. In the majority of studies, the documented daily intake levels have been over 150 g of ethanol (the equivalent of 1 pint of 80-proof spirits), often in the range of 250-300 g. Other potential risk factors such as malnutrition are rarely considered, and little information is available on the effects of more moderate daily intake. The liver emerges as the organ most vulnerable to regular alcohol use, with the hazardous range beginning at a daily intake of 80-100 g of ethanol. There is some evidence of beneficial effects, especially in the elderly, of daily intakes of 15-30 g, and epidemiological evidence exists of a lower incidence of myocardial infarction in those with a daily intake approximating 56 g. More information is needed on chronic intake-effect relationships, particularly at levels below 150 g.

4151 CHEMICAL NATURE OF ALCOHOLIC HYALIN.

(Eng.) Luisada-Opper, A. V.; Kanagasundaram, N.; Leevy, C. M. (Coll. Medicine and Dentistry of New Jersey, Newark, NJ 17103). *Gastroenterology* 73(6):1374-1376; 1977.

The nature of protein components present in a purified alcoholic hyalin preparation was investigated. Alcoholic hyalin was prepared from postmortem livers of patients with alcoholic liver disease and purified by discontinuous sucrose density gradient ultracentrifugation. The purified protein preparation contained about 12% reducing sugar, the remainder being protein. Gel filtration on a Sephadex 4B column showed the presence of three peaks. The material in each peak contained acetylglucosamine, hexosamine, and deoxysugar (calculated as rhamnose). That these protein components are glycoprotein in nature was confirmed by polyacrylamide gel electrophoresis followed by scanning the gels at 280 nm and then at 520 nm (after staining the gels with PAS base reagent for the presence of carbohydrate).

4152 ALCOHOLIC HYALIN ANTIGEN (AHAg) AND ANTIBODY (AHAb) IN ALCOHOLIC HEPATITIS.

(Eng.) Kanagasundaram, N.; Kakumu, S.; Chen, T.; Leevy, C. M. (Coll. Medicine and Dentistry of New Jersey, 100 Bergen St., Newark, NJ 17103). *Gastroenterology* 73(6):1368-1373; 1977.

Serum and tissue from subjects without liver disease and from patients with various hepatic diseases were studied by complement fixation (CF) and immune adherence (IA) hemagglutination tests to characterize alcoholic hyalin (AH) isolated from human postmortem liver, to determine the diagnostic value of AH antigen (AHAg), and to investigate the occurrence and significance of tissue immune complexes in alcoholic hepatitis. Isolated purified AH was used to produce AH antibody (AHAb) in rabbits. Rabbit antiserum was added to heat-inactivated human serum to detect AHAg; purified AH was added to serum and tissue eluates to detect AHAb. AHAg was present in the serum of each of 15 patients with early phase alcoholic hepatitis in CF titers of 8 to 64 and IA titers of 16 to 2,048. AHAg became negative within 3 to 5 weeks with abstinence from alcohol and was followed by transient appearance of AHAb. AHAb was present in 11 patients with advanced phases of alcoholic hepatitis in CF titers of 8 to 640 and IA titers of 16 to 4,096. Four patients in this group exhibited concomitant AHAb and AHAg. Investigations of liver tissue eluate reveal that patients with advanced alcoholic hepatitis or active alcoholic cirrhosis have AHAg-reactive immune complexes containing IgG and IgA.

4153 CLINICOPATHOLOGICAL STUDY OF ALCOHOLIC LIVER INJURY IN JAPAN [Abstract]. (Eng.) Inoue, K.; Sato, E. (Toyama Medical and Pharmaceutical Sch., Tohama, Japan). *Gastroenterol. Jpn.* 12(4):340; 1977.

4154 A PATHOGENESIS OF ALCOHOLIC LIVER INJURY [Abstract]. (Eng.) Okabe, K. (St. Marianna Univ. Sch. Medicine, Kanagawa, Japan). *Gastroenterol. Jpn.* 12(4):339-340; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

4155 HEPATIC KINETICS OF ^{99m}TECHNETIUM SULFUR COLLOID IN CIRRHOSIS. (Eng.) George, E. A.; Shields, J. B.; Cabal, E. C.; Schulz, R. C.; Donati, R. M. (St. Louis Veterans Admin. Hosp., St. Louis, MO 63125). *J. Nucl. Med. All. Sci.* 21 (3):107-112; 1977.

Experience with an index of hepatic arterial and portal venous circulation determined by analysis of the kinetic sequence of events that followed the peripheral venous injection of ^{99m}technetium (^{99m}Tc) sulfur colloid in 97 subjects is presented. Evaluation of portal hemodynamics during the first hepatic transit of ^{99m}Tc sulfur colloid by sequential hepatic imaging (visual evaluation) and by computer-assisted calculation of percent portal extraction of the radiocolloid suggested good correlation with the clinical entity. Percent portal hepatic extraction of sulfur colloid correlated well with corrected hepatic wedge pressure obtained in 20 control patients and in 42 patients with uncomplicated cirrhosis. Slight to moderately elevated corrected hepatic wedge pressure appeared to inversely parallel the degree of diminished percentage of portally extractable radiocolloid. Portasystemic shunting, which tends to normalize corrected hepatic wedge pressure, may decrease further portal extraction until undetectability, which, however, compares better with the abnormal hepatic hemodynamics at hand than a normal hepatic wedge pressure gradient. Similarly, prehepatic portal hypertension secondary to portal or mesenteric thrombosis was not reflected by an elevated corrected hepatic wedge pressure but was well demonstrated by the radionuclide technique. The data suggest that the technique of the calculation of percentage of portally extractable sulfur colloid could serve as a sensitive indicator for the detection, progression, or recovery from hepatic hemodynamic abnormalities. The technique, however, does not offer an index of portal pressure gradients in advanced cirrhosis and postsurgical portasystemic shunting.

4156 IS PRIMARY BILIARY CIRRHOSIS AN IMMUNE COMPLEX DISEASE? (Eng.) Thomas, H. C.; Potter, B. J.; Sherlock, S. (Royal Free Hosp., London, England). *Lancet* 2(8051):1261-1263; 1977.

The possibility that primary biliary cirrhosis is related to immune complex liver injury is discussed. Large immune complexes are present in the circulation of patients with primary biliary cirrhosis and result in the activation of complement by the classical pathway. Such large complexes are capable of producing tissue damage. The granulomatous lesions surrounding the small bile ducts within the liver of patients with primary biliary cirrhosis and the vasculitis, rheumatoid arthritis, and associated lesions are all compatible with immune complex injury. It is postulated that such large complexes could be formed in the vicinity of the bile ducts by an antigen absorbed from the bile or biliary epithelium. Complexes reaching the systemic circulation might be responsible for the associated extrahepatic diseases.

4157 ASSOCIATION OF HUMAN LEUKOCYTE ANTIGEN (HLA)-B5 AND -BW22-J WITH HEPATIC CIRRHOSIS OF APPARENTLY UNKNOWN ETIOLOGY. (Eng.) Ohkubo, A.; Okimoto, K.; Iwasaki, Y.; Kosaka, K.; Juji, T.; Tohyama, H. (Faculty Medicine, Univ.

Tokyo, Tokyo 113, Japan). *Tohoku J. Exp. Med.* 123 (3):257-263; 1977.

The association of histocompatibility antigens HLA-BW22-J (a Japanese-specific HLA antigen) and HLA-B5 with hepatic cirrhosis of unknown etiology was studied in 29 patients with histologically proven hepatic cirrhosis (based on needle biopsy) and in 128 healthy controls, all randomly selected. HLA types were determined for the first (A) and the second (B) loci by the lymphocytotoxicity technique. Of the 29 patients, 5 were positive for hepatitis B surface antigen (HBsAg), and 4 had cirrhotic patients in their families, 2 of which cases were HBsAg-positive. Twenty-one of the 29 patients were positive for HLA phenotype B5 and 11 for phenotype BW22-J. Forty-one of the 128 controls were positive for B5 and 13 for BW22-J. The differences in frequencies of B5 and BW22-J between the patients and the controls were statistically significant ($p<0.003$ and relative risk=5.57 for B5, and $p<0.01$ and relative risk=5.40 for BW22-J). The results suggest that a predisposition linked to HLA-associated genes plays an important role in development of hepatic cirrhosis of unknown etiology in Japan; further studies are required that will bear upon prevention and treatment of this entity.

4158 RELATIVE CONCENTRATIONS OF INDIVIDUAL NONSULFATED BILE ACIDS IN THE SERUM AND BILE OF PATIENTS WITH CIRRHOSIS.

(Eng.) Struthers, J. E., Jr.; Mehta, S. J.; Kaye, M. D.; Naylor, J. L. (Veterans Admin. Hosp., 1055 Clermont St., Denver, CO 80220). *Am. J. Dig. Dis.* 22(10):861-865; 1977.

The relative concentrations of individual nonsulfated bile acids were determined in samples of serum and bile obtained simultaneously from 16 patients with biopsy proven alcoholic cirrhosis. A highly significant ($p<0.001$) correlation was found between the fasting relative concentrations of each of the three major bile acids (cholic, chenodeoxycholic, and deoxycholic) in serum and bile. This relationship persisted after manipulation of bile acid pools produced by feeding individual bile acids (250, 100, and 100 mg, 4x/day for cholic, deoxycholic, and taurodeoxycholic acids, resp.) for 4 days. It is concluded that the relative concentrations of individual nonsulfated bile acids in serum accurately reflect those in bile and that measurement of individual serum bile acids may be used for screening and serial determination purposes. In particular, low levels of biliary deoxycholate can be reliably predicted by serum measurements.

4159 FIBRIN-FIBRINOGEN DEGRADATION PRODUCTS IN HEPATIC CIRRHOSIS.

(Eng.) Bulajic, M.; Kovacevic, N.; Lalic, M.; Rolovic, Z. (Medical Faculty, Univ. Beograd, Beograd, Yugoslavia). *Acta Med. Iugosl.* 31(4):333-338; 1977.

To investigate the possible role of disseminated intravascular coagulation in the pathogenesis of hemorrhage in hepatic cirrhosis, the severity of liver damage was correlated with the concentration of serum fibrin-fibrinogen degradation products in 14 patients with compensated or noncompensated liver cirrhosis. Increased fibrin-fibrinogen degradation products were found only in three of the six patients with alcoholic cirrhosis. Although there were differences in the level of fibrin-fibrinogen degradation products in patients with decompensated and compensated cirrhosis, this difference was not statistically significant. It is concluded that the frequency of the elevated fibrin-fibrinogen degradation products in cirrhosis is low. Other factors must be sought to account for hemorrhage in cirrhosis.

4160 ASSOCIATION OF ABNORMAL FIBRIN POLYMERISATION WITH SEVERE LIVER DISEASE.

(Eng.) Green, G.; Poller, L.; Thomson, J. M.; Dymock, I. W. (Rancho Los Amigos Hosp., Downey, CA 90242). *Gut* 18(11):909-912; 1977.

To investigate the frequent occurrence of abnormal fibrin polymerization reported in patients with liver disease, fibrin polymerization was studied in 68 patients with cirrhosis or chronic active liver disease. Thirty-three of these patients demonstrated impairment of this phase of blood coagulation. When other tests of liver function were compared in patients with this abnormality and in those in whom fibrin polymerization was normal, the former group demonstrated significantly reduced albumin concentrations ($p<0.0002$), raised bilirubin and aspartate amino transferase levels ($p<0.0006$ and <0.003, resp.), and greater prolongation of the one-stage prothrombin time ($p<0.001$) with more marked reduction in factor VII levels ($p<0.002$) compared with the latter patients. It is concluded that defective fibrin polymerization occurring in patients with liver disease indicates the presence of severely impaired hepatocellular function. This fact might account for the grave prognosis reported in cirrhotic patients with abnormal fibrin polymerization who also suffer bleeding from gastroesophageal varices.

4161 HEPARIN ELIMINATION IN PATIENTS WITH LIVER CIRRHOSIS.

(Eng.) Teien, A. N. (Aker Hosp., Oslo 5, Norway). *Thromb. Haemostas.* 38(3):701-706; 1977.

Heparin metabolism was studied in six patients with liver cirrhosis and normal renal function and in six normal subjects. Heparin (100 U/kg) was injected i.v., and heparin concentration in plasma was determined by polybrene titration. The mean heparin half-life was 117.8 min in the patients as compared to 74.0 min in the controls ($p=0.02$). The heparin half-life was correlated to galactose half-life in the patients ($r=0.83$, $p=0.05$). The findings suggest that heparin is metabolized in the liver. There was a significant decrease in antithrombin III activities in the controls, but not in the patients. A possible explanation may be that the normal liver removes heparin bound to antithrombin III, and that this function is impaired in liver cirrhosis.

4162 ABSORPTION, HYDROXYLATION, AND EXCRETION OF VITAMIN D_3 IN PRIMARY BILIARY CIRRHOSIS.

(Eng.) Krawitt, E. L.; Grundman, M. J.; Mawer, E. B. (Dept. Medicine, Univ. Vermont, Burlington, VT). *Lancet* 2(8051):1243-1249; 1977.

The absorption of a p.o. dose of ^{3}H-vitamin D_3 and the 25-hydroxylation of i.v. administered ^{14}C-vitamine D_3 were studied simultaneously in six patients with primary biliary cirrhosis and in four controls. Vitamin D_3 (3 μg, 8 μCi, p.o.) was poorly absorbed by four of the six patients with primary biliary cirrhosis; absorption was negatively correlated with fecal fat excretion. 25-Hydroxylation of p.o. or i.v. vitamin D_3 was not impaired in the patients compared with controls of similar vitamin D nutritional status. Urinary radioactivity derived from the i.v. dose of vitamin D_3 (25 μg, 2 μCi) was significantly greater in patients than in controls (mean excretion 9.1 ± 2.6% of injected dose in patients, 2.8 ± 0.4% in controls) and was positively correlated with the serum bilirubin concentration ($r=0.92$, $p=0.005$). Urinary excretion may lead to loss of administered and endogenous vitamin D and thus contribute to vitamin D deficiency in patients with primary biliary cirrhosis.

4163 DETECTION OF HEPATOMA IN LIVER CIRRHOSIS.

(Eng.) Moreau, R.; Soussaline, F.; Chauvaud, S.; Parmentier, C.; Di Paola, R.; Charbord, P.; *et al.* (Laboratoire des Isotopes, Inst. Gustave-Roussy, F-94800 Villejuif, France). *Eur. J. Nucl. Med.* 2(3):183-188; 1977.

Double isotope scintigraphies with ^{67}Ga citrate and ^{99m}Tc sulfur colloid were used with digital subtraction, after simultaneous recording of ^{99m}Tc and ^{67}Ga data on magnetic tape (by an interface) in 33 cirrhotic patients for the detection of hepatoma. Hepatoma was diagnosed histologically in six cases. Using this double isotope technique, there were no false-positives in subtraction scintigrams. There was one false-negative because of the lack of significance in the subtracted image for one of the six patients with liver cancer. For three of the six patients with hepatoma, the ^{67}Ga scintigram showed an increased uptake in the tumor area. For the three other cases, the ^{67}Ga uptake was equilibrated throughout the liver scintigraphy. The subtraction technique is of greatest value in cases where the ^{67}Ga scintigram shows no increased activity, as it permitted the diagnosis of hepatoma in two cases.

4164 SERUM Gc SYSTEM IN LIVER CIRRHOSIS AND HEPATOMA.

(Eng.) Theodoropoulos, G.; Rigatos, G.; Babionitakis, A.; Archimandritis, A.; Fertakis, A.; Melissinos, K. (2, Dryadon St., Chalandri-Athens, Greece). *Hum. Genet.* 39(2):225-228; 1977.

Serum group specific component (Gc) polymorphism was studied in 85 Greek patients with liver cirrhosis, in 65 with cirrhosis plus hepatoma, and in 40 with hepatoma without cirrhosis. Six hundred unrelated healthy Greeks served as controls. The Gc 1-1 phenotype was found more frequently ($p<0.0005$-0.05) in patients with cirrhosis (with or without hepatoma), and the incidence of the Gc^1 allele was significantly higher ($p<0.001$-0.05) in patients with cryptogenic hepatitis B surface antigen (HBsAg)-negative cirrhosis. On the other hand, the Gc 2-2 phenotype was found about three times more frequently in patients who had hepatoma without cirrhosis, and the incidence of the Gc^2 allele was significantly higher in the same group than in the controls. The Gc^1 and the Gc^2 alleles apparently predispose, under the influence of various factors, the development of cryptogenic cirrhosis and hepatoma without cirrhosis, resp.

4165 ENCEPHALOPATHY IN PATIENTS WITH CIRRHOSIS OF THE LIVER. A NEUROPSYCHOLOGICAL STUDY.

(Eng.) Elsass, P.; Lund, Y.; Ranek, L. (Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 13(2):241-247; 1978.

Neuropsychological tests and clinical ratings of consciousness level were performed in 30 patients with encephalopathy due to biopsy-proven liver cirrhosis of various etiology. The results were compared to test norms for patients with diffuse cerebral lesions to give a neuropsychological description of the encephalopathic state of patients with these two entities and to investigate whether the neuropsychological characterization of the encephalopathic course differs between patients with a portacaval anastomosis and patients without this operation. The level of consciousness was evaluated on the basis of such criteria as blurred speech; slow, inert reactions; sleepiness; psychomotor uneasiness; apathy; lack of spontaneity; absentmindedness; emotional instability; euphoria; and bizzare behavior. Neuropsychological tests included subtraction, block design/hidden patterns, visual gestals, digit span, word fluency, and story recall/picture recognition. All patients were tested once with both tests to investigate the state of encephalopathy. To investigate the course of encephalopathy, eight patients with portacaval anastomosis were also tested after the surgery, and eleven unoperated patients were tested once a week during 3 weeks. The neuropsychological tests were graded according to the norms for diffuse cerebral lesion and showed that three-fifths of the patients had intellectual impairments while the remaining two-fifths had an intact level of functioning. However, according to clinical ratings, one-third showed a suspect lowered level of consciousness without general intellectual impairment, while one-tenth had slight intellectual impairment but a normal level of consciousness. In all cases of lowered level of consciousness, the function of attention was impaired; the functions of memory and abstraction were less impaired than attention. In the eight patients with portacaval anastomosis, the level of consciousness varied, generally deteriorated in parallel with liver function, and could vary hourly; this group showed significant ($p<0.01$-0.02) reductions in the scores of memory and abstraction tests, which is characteristic of intellectual impairment in diffuse cerebral lesions. The patient group without portacaval anastomosis showed variations in level of consciousness similar to those of the operated group but no significant deteriorations in any of the test results within the investigations performed. The level of attention is an important part of the clinical picture in encephalopathy due to liver cirrhosis and differentiates well between patients with diffuse cerebral lesions and those with hepatic encephalopathy. The cerebral effect of portacaval anastomosis appears as an intellectual deterioration and produces a different course of cerebral affection than that seen in patients without this operation.

4166 EFFECT OF VEGETABLE AND ANIMAL PROTEIN DIETS IN CHRONIC HEPATIC ENCEPHALOPATHY.

(Eng.) Greenberger, N. J.; Carley, J.; Schenker, S.; Bettinger, I.; Stamnes, C.; Beyer, P. (Kansas Univ. Medical Center, 39 and Rainbow, Kansis City, KS 66103). *Am. J. Dig. Dis.* 22(10):845-855; 1977.

The effect of a vegetable protein diet as compared to an animal protein diet on standard clinical and laboratory parameters was examined in three patients with chronic hepatic encephalopathy. To evaluate more objectively the effects of vegetable or animal protein diets, an hepatic encephalopathy index was developed, and this included the following parameters: fetor hepaticus, asterixis, stage of hepatic coma (Parson-Smith), arterial ammonia levels, EEG, Reitan trail test, and any reduction or improvement in dietary protein tolerance. In controlled, randomized, single-blind trials, it was found that a vegetable protein diet resulted in overall clinical improvement, decreased hepatic encephalopathy index scores, decreased arterial ammonia levels, improved performance on intellectual tasks, and in one case, markedly improved protein tolerance. Further, the beneficial effects of a vegetable protein diet were enhanced by the use of lactulose. These studies do not provide a clear-cut definition of the mechanism for the observed beneficial effects of vegetable protein in chronic hepatic encephalopathy. However, the most plausible explanation is that vegetable protein diets contain lower amounts of certain amino acids and other materials that may be important in the pathogenesis of hepatic encephalopathy.

4167 INCREASED CONCURRENCE OF CIRRHOSIS AND BACTERIAL ENDOCARDITIS: A CLINICAL AND POSTMORTEM STUDY.

(Eng.) Snyder, N.; Atterbury, C. E.; Correia, J. P.; Conn, H. O. (Veterans Admin. Hosp., West Haven, CT 06516). *Gastroenterology* 73(5):1107-1113; 1977.

To test the hypothesis that spontaneous bacterial peritonitis in cirrhosis is caused by the infection of pre-existing ascites by blood borne bacteria (making other sites vulnerable to infection), the frequency of bacterial endocarditis in cirrhotic and noncirrhotic patients was determined. At autopsy, bacterial endocarditis was found in 1.8% of 557 cirrhotic patients compared to 0.9% of 3,658 noncirrhotic patients ($p<0.06$), despite the expected negative association predicted by Berkson's hypothesis. There was no such association between bacterial endocarditis and either myocardial infarction or emphysema. There were highly significant negative associations between glioblastoma multiforme and cirrhosis ($p<0.01$), myocardial infarction ($p<0.01$), and emphysema ($p<0.02$). Among the 41,151 patients admitted to the hospital, bacterial endocarditis was observed in 0.1% of the noncirrhotic patients compared to 0.34% of the cirrhotic patients ($p<0.001$). The bacterial endocarditis in cirrhosis differed from the conventional syndrome in several ways. Nonrheumatic heart disease, especially calcific aortic stenosis, occurred more frequently in noncirrhotic than in cirrhotic patients. Enteric bacteria are responsible for a higher percentage and α-hemolytic streptococci for a lower percentage of cirrhotic bacterial endocarditis than in conventional bacterial endocarditis. The association between cirrhosis and bacterial endocarditis supports the postulated hematogenous route of infection in spontaneous bacterial peritonitis.

4168 HEPATOMEGALY AND RECURRENT ASCITES IN AN 11-YEAR-OLD BOY.

(Eng.) Tang, T. T.; Davis, S.; Keelan, M. H.; Lepley, D., Jr.; Babbitt, D. P. (Milwaukee Children's Hosp., P.O. Box 1997, Milwaukee, WI 53201). *J. Pediatr.* 91(6):1015-1020; 1977.

A case of hepatomegaly and recurrent ascites in an 11-yr-old boy is described. The boy was admitted to a hospital because of increasing abdominal girth. A liver scan suggested a "lymphatic disease" in the left lobe. At exploratory laparotomy the portal pressure was 260 mm H_2O; liver biopsy showed cirrhosis of unknown etiology. Upon a second admission 1 month later, the boy had a proturberant abdomen and the liver edge extended 5 cm below costal margin. At laparotomy, 1,300 ml of clear ascitic fluid was aspirated; normal venous flow and portal pressure were observed in the liver. A liver biopsy was diagnosed as hepatoportal sclerosis with focal cirrhosis; a liver scan was suggestive of cirrhosis. After discharge, the boy's condition remained stable, but 4 months later he was readmitted for paracentesis, and 4,300 ml of amber clear fluid was aspirated. He was treated with hydrochlorothiazide and multivitamins with iron but the ascites recurred. Chest roentgenograms showed minimally enlarged heart and prominent superior vena cava. On the basis of the information available the diagnoses considered were idiopathic cirrhosis, alpha$_1$-antitrypsin deficiency, constrictive pericarditis, and cardiac myxoma. The possibility of constrictive pericarditis was confirmed by careful examination, including inspection of neck veins and determination of atrial, ventral, and hepatic wedge pressures. A thoracotomy was performed, and the pericardium was removed except for a minute shelf on the back of the left atrium. About 4 months later, intracardiac pressures had returned to normal, and the ascites had completely subsided. One year later, the pressure contour in the right ventricle had become nearly normal, and the early diastolic dip had disappeared. Retrospectively, veno-occlusive disease was suspected on the basis of liver biopsies, but histological and microbiological examination of pericardium gave no clues of possible etiology of constrictive pericarditis. This classic case of idiopathic constrictive pericarditis is an extremely important case for clinical practice, illustrating the critical nature of careful physical examination that would have lead to the correct diagnosis sooner.

4169 HYPOXEMIA OF CIRRHOSIS: DETECTION OF ABNORMAL SMALL PULMONARY VASCULAR CHANNELS BY A QUANTITATIVE RADIONUCLIDE METHOD.

(Eng.) Wolfe, J. D.; Tashkin, D. P.; Holly, F. E.; Brachman, M. B.; Genovesi, M. G. (Univ. California Sch. Medicine, Los Angeles, CA 90024). *Am. J. Med.* 63 (5):746-754; 1977.

The pathophysiology of hypoxemia (arterial oxygen tension [PaO_2] 48.5-68 mm Hg) in three patients with hepatic cirrhosis was investigated using conventional cardiopulmonary tests and a special radionuclide technique for the detection of shunting through small dilated pulmonary vessels. Pulmonary function tests revealed normal spirometry and lung volumes, normal closing volume and single-breath nitrogen washout, abnormal diffusing capacity (41-68% of predicted), increased venous admixture of 100% oxygen (8.1-29%), and a decrease in PaO_2 after change from the supine to the sitting position and after exercise. Cardiac catheterization revealed normal pulmonary arterial pressures at rest and during exercise, increased cardiac outputs, and no intracardiac shunts. Chest roentgenograms and pulmonary angiograms were within normal limits. Using a quantitative radionuclide technique, 10%, 46%, and 70.5% of i.v.-injected technetium 99m-macroaggregated albumin (^{99m}Tc-MAA) particles traversed the pulmonary vasculature and lodged in end-organ systemic capillary beds in the three patients with cirrhosis compared with 6% or less in eight controls. The results document the presence of dilated pulmonary capillaries and/or arteriovenous communications that are too small to be detected angiographically. These abnormal vascular channels can account for the hypoxemia observed in patients with liver cirrhosis, primarily on the basis of diffusion/perfusion imbalance and to a lesser extent by true shunting.

4170 DISPOSITION OF NAFCILLIN IN PATIENTS WITH CIRRHOSIS AND EXTRAHEPATIC BILIARY OBSTRUCTION.

(Eng.) Marshall, J. P., II; Salt, W. B.; Elam, R. O.; Wilkinson, G. R.; Schenker, S. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37203). *Gastroenterology* 73(6):1388-1392; 1977.

The effect of cirrhosis and extrahepatic biliary obstruction on the pharmacokinetics of nafcillin was studied in 12 controls, 12 patients with cirrhosis, and 5 patients with extrahepatic biliary obstruction. The plasma clearance of nafcillin in controls was 583 ± 144.2 ml/min and fell strikingly to 291 ± 147.6 and 163 ± 56.3 ml/min in patients with cirrhosis and extrahepatic obstruction, resp. ($p<0.001$). In the latter two groups, nafcillin excreted in urine increased from about 30% to 50% of the administered dose ($p<0.02$), suggesting that renal disease superimposed on hepatic disease would further decrease overall nafcillin clearance. The depression of nafcillin clearance with hepatobiliary disease did not correlate with any conventional liver laboratory test. The initial volume of distribution of nafcillin was unaltered, but at steady state there was a significant reduction in the distribution volume in the patients with liver disease. Accordingly, the impairment in drug elimination, as assessed by its plasma clearance, was underestimated by the prolongation of the nafcillin elimination half-life, which was 1.02 ± 0.20 hr in controls and 1.23 ± 0.31 ($p>0.05$) and 1.73 ± 0.44 hr ($p<0.03$), resp., in patients with cirrhosis and extrahepatic obstruction.

4171 KALLIKREIN-KININ AND RENIN-ANGIOTENSIN SYSTEMS IN FUNCTIONAL RENAL FAILURE OF CIRRHOSIS OF THE LIVER.

(Eng.) Wong, P. Y.; Talamo, R. C.; Williams, G. H. (Albany Medical Coll., Albany, NY 12208). *Gastroenterology* 73(5):1114-1118; 1977.

The possibility that abnormal kallikrein-kinin and renin-angiotensin systems may be responsible for functional renal failure was investigated in 15 patients with liver cirrhosis. Seven of these patients (control group) had persistent ascites, prothrombin time more than 3 sec above controls, and normal blood urea nitrogen and serum creatinine. The remaining eight patients had hepatorenal (HR) syndrome (functional renal failure) in alcoholic liver disease. All patients had been on a low sodium (<10 mEq/24 hr) diet for 5 to 6 days. Fasting supine, overnight blood samples were then drawn between 8 and 10 AM. The mean plasma prekallikrein as determined by the tosyl arginine methyl ester (TAMe) esterase method for control patients was 11.6 ± 2.8, whereas that of the HR group was 2.5 ± 1 μM/hr, $p<0.007$ (normal: 95 ± 3.75). The mean plasma bradykinin for the controls was 1 ± 0.44 and that of the HR group was 0.23 ± 0.01 ng/ml, $p<0.001$ (normal: 3.5 ± 1). The mean plasma renin activity for the control group was 26.4 ± 12 and that of four patients in the HR group was 50.4 ± 23 ng/ml/hr (normal: 5.28 ± 1), the difference was not significant despite the elevation in HR patients. The mean angiotensin II for the control group was 94.4 ± 33 and that of the HR group was 356.5 ± 122 pg/ml, $p<0.03$ (normal: 57 ± 7). The combined effects of excess in vasoconstrictor hormone (angiotensin II) and deficiency of a renal vasodilator (bradykinin) may be etiologic in the pathogenesis of HR syndrome.

4172 THE DIAGNOSIS OF THE SITE OF UPPER GASTROINTESTINAL HAEMORRHAGE IN PATIENTS WITH ESTABLISHED PORTAL HYPERTENSION.

(Eng.) Mitchell, C. J.; Jewell, D. P. (St. James' Hosp., Leeds LS9 7TF, England). *Endoscopy* 9(3):131-135; 1977.

e findings of 75 endoscopies performed in 60 pa-
ents known to have esophageal varices and who
esented with further upper gastrointestinal hem-
rhage during the previous 72 hr are presented. A
e of active bleeding was found at 50 of the 75
aminations. Endoscopy was performed within 3 hr
the last bleeding episode in 21 patients, and
e site of hemorrhage was detected in all of them.
e bleeding site was determined in only four of
ght patients who were endoscoped 24-48 hr after
morrhage. Variceal bleeding alone was seen in
of these 50 examinations, while only six patients
re bleeding from mucosal lesions alone. Both
rices and mucosal lesions were bleeding in four
tients. An adult end-viewing duodenoscope was
ed in 45 endoscopies, and bleeding from esopha-
al varices restarted during the procedure in three
tients; one patient remained unconscious for 24 hr
llowing i.v. diazepam administration. A pedia-
c endoscope was used for 30 examinations, and a
l examination was achieved in each patient. No
dation was required, and the procedure was free
complications. The pediatric endoscope is
garded as the instrument of choice for patients
own to have portal hypertension and who present
th upper gastrointestinal hemorrhage.

73 PORTAL HYPERTENSION AND TRANSHEPATIC EMBOLISATION OF GASTRO-OESOPHAGEAL VAR-
S. (Eng.) Casselden, P. A. (Royal Free
p., London, England). *Radiography* 43(514):
-228; 1977.

e pathology of portal hypertension is outlined
gether with the formation and treatment of gastro-
ophageal varices. Portal hypertension is invari-
y caused by an obstruction of the portal vein
newhere along its course and may anatomically be
assified into pre- and postsinusoidal intra- and
trahepatic obstruction. When the portal circula-
on is obstructed either extra- or intrahepati-
lly, it is normal to find the development of a
llateral circulation carrying portal blood to the
stemic veins. The treatment of esophageal and
stric varices may be accomplished by the follow-
g procedures: blood transfusion; the administra-
on of vasopressin to lower the portal pressure;
e insertion of a Sengstaken tube and balloon;
rgical intervention that includes localized
vascularization of the varices, portasystemic
unts, and subcardiac porta-azygos disconnection;
literation of varices by esophagoscopy; and trans-
patic portography. Transhepatic portography to-
ther with the selective catheterization of esoph-
eal and gastric varices has been developed with
couraging short-term results. Although emboliza-
on of varices does not cure portal hypertension
d is not the ideal treatment since further col-
teral veins may form, the flow in existing veins
interrupted, and it is hoped that the blood will
ss through other veins less prone to bleeding,
., the renal vein. Patients selected for em-
lization of varices all have a history of exten-
ve hemorrhage and are considered at high risk with
or operative and postoperative prognosis. The
ly contraindications to this technique appear to
be excessive bleeding, hepatic mass, or hydatid disease. Although no control series has been completed for selective catheterization and obliteration of bleeding varices, all cases that have been followed with transplenic venography reveal that the portal vein is patent and that the majority of successfully embolized varices remain thrombosed. The longest follow-up to date is 1 yr, and no further hemorrhaging has occurred in this patient.

4174 OPERATIVE RESULTS IN PORTAL HYPERTENSION WITH BLEEDING OESOPHAGEAL VARICES. (Eng.)

Bergan, A.; Flatmark, A. (Natl. Hosp. Norway, Univ. Clinic, Oslo, Norway). *Scand. J. Gastroenterol.* 12(6):677-682; 1977.

The results of surgery in 81 patients who were treated during a 15-yr period for bleeding esophageal varices complicating portal hypertension are presented. Nearly 90% had liver cirrhosis, and 21% were alcoholics. Sixty-seven portasystemic shunts were performed in 63 patients; 11 of these were emergency procedures. The overall operative mortality in electively shunted patients was 10.7%. Even in those with the most severe liver insufficiency (child's group C), operative mortality was below 20%. Operative mortality in the elective cases was closely correlated to peroperative bleeding. Only 1 of 45 patients needing less than 10 units of blood peroperatively died, while mortality in the multitransfused group was 45.5%. Both patients who survived urgent shunt surgery were operated on early, i.e., before they had received 5 units of blood each.

4175 CIRRHOTIC PORTAL HYPERTENSION: MORBIDITY OF CONTINUED ALCOHOLISM. (Eng.)

Pande, N. V.; Resnick, R. H.; Yee, W.; Eckardt, V. F.; Shurberg, J. L. (Lemuel Shattuck Hosp., 170 Morton St., Boston, MA 02130). *Gastroenterology* 74(1):64-69; 1978.

The morbidity of continued alcoholism was examined in 172 cirrhotic patients who had been randomized for participation in controlled trials of portacaval shunts. Of 159 patients surviving more than 30 days, 76 continued drinking (group A), 68 abstained (group B), and 15 (group C) were chronically institutionalized (without potential access to alcohol). The mean number of days in hospital (postrandomization) and the prevalence of bleeding varices, ascites, and encephalopathy were similar for groups A and B ($p>0.05$ for each comparison). Jaundice at hospital readmission, however, occurred in 50% of group A but in only 28% of group B ($p<0.01$). Mortality and complication rates were substantially greater in group C than in groups A or B, emphasizing the significance of progressive liver disease in institutionalized patients. Although continued alcoholism was associated with recurrent jaundice, a major impact on other criteria of morbidity was not demonstrated.

4176 LOWER ESOPHAGEAL SPHINCTER FUNCTION IN CIRRHOSIS. (Eng.) Nebel, O. T. (530 Lomas Santa Fe Drive, Solana Beach, CA 92075). *Am. J. Dig. Dis.* 22(12):1101-1105; 1977.

Lower esophageal sphincter (LES) function in cirrhosis was evaluated in 10 cirrhotic patients without ascites, 5 cirrhotic patients with ascites, and 10 controls using an infused manometric system. LES pressure (LESP) in the subjects with cirrhosis (22 + 1 mm Hg) was not significantly ($p>0.05$) different from that of the control subjects (21 ± 1 mm Hg) but was significantly ($p<0.01$) greater than the LESP in the subjects with cirrhosis and ascites (16 ± 2 mm Hg). There was no significant difference in LES response to i.v. pentagastrin, i.v. edrophonium (80 μg/kg), or straight-leg raising in the three groups. After loss of ascitic fluid, LESP significantly ($p<0.01$) increased change in pressure ($\Delta P=9 \pm 3$ mm Hg) and gastric pressure (GP) significantly ($p<0.01$) decreased ($\Delta P=8 \pm 2$ mm Hg). The changes in LESP and GP revealed a significant ($r=0.83$, $p<0.001$) linear correlation. These data indicate that cirrhosis is associated with normal LES function, and that the mechanism of lowered LESP with ascites may be the inability of the LES to maintain a sustained response to chronic increases in GP.

4177 INCIDENCE OF LIVER CIRRHOSIS IN 16 AREAS OF THE U.S. [Abstract]. (Eng.) Garagliano, C. F.; Mendeloff, A. I.; Lilienfeld, A. M. (Dept. Epidemiology, Johns Hopkins Univ., Baltimore, MD). *Gastroenterology* 72(5, Part 2):1060; 1977.

4178 SUBCLINICAL HEPATIC ENCEPHALOPATHY: DETECTION, PREVALENCE, AND RELATIONSHIP TO NITROGEN METABOLISM [Abstract]. (Eng.) Rikkers, L.; Jenko, P.; Rudman, D.; Freides, D. (Emory Univ. Sch. Medicine, Atlanta, GA). *Gastroenterology* 72(5, Part 2):1119; 1977.

4179 DOES PORTAL HYPERTENSION CONTRIBUTE TO THE FEMINIZATION OF ALCOHOLIC MEN [Abstract]? (Eng.) Van Thiel, D. H.; Gavaler, J. S.; Slone, F.; Smith, W. I., Jr.; Lester, R.. (Dept. Medicine, Univ. Pittsburgh, Pittsburgh, PA). *Gastroenterology* 72(5, Part 2):1144; 1977.

See also, 3695, 3844, 3847, 4085, 4087, 4104, 4109, 4110, 4136, 4147, 4149.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

4180 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY (ERC) IN SURGICAL EMERGENCIES. (Eng.) Safrany, L.; Van Husen, N.; Kautz, G.; Wittrin, G.; Clemens, M.; Weitemeyer, R. (Reinhard-Nieter-Krankenhaus, 2940 Wilhelmshaven, W. Germany). *Ann. Surg.* 187(1):20-23; 1978.

The cases of 12 patients, presenting with an acute abdomen of suspected biliary tract origin, who underwent endoscopic retrograde cholangiography (ERC) are discussed, and 6 cases are presented. Eight patients had either traumatic, spontaneous, or postoperative biliary tract fistulas with five leading to the peritoneal cavity, one to the colon, one to the bronchial tree, and one to the liver parenchyma from a ruptured gallbladder. Each was confirmed by ERC. Four patients with jaundice following traumatic rupture of the liver had a pathological communication between the intrahepatic biliary tracts and the hepatic vascular system. It is concluded that ERC is a reliable method for obtaining precise localization of biliary tract problems in surgical emergencies both pre- and postoperatively.

4181 BILIARY ATRESIA: HISTOPATHOLOGIC OBSERVATIONS AND REFLECTIONS UPON ITS NATURAL HISTORY. (Eng.) Bill, A. H.; Haas, J. E.; Foster, G. L. (Children's Orthopedic Hosp. and Medical Center, 4800 Sand Point Way, Seattle, WA 98105). *J. Pediatr. Surg.* 12(6):977-982; 1977.

To investigate the etiology of biliary atresia, operative liver biopsies and specimens of the extrahepatic ducts and porta hepatis were studied in 12 cases of biliary atresia. In all cases, the liver showed giant cell transformation and inflammation with mononuclear cells and neutrophils. Most had other features of neonatal hepatitis, including hepatocyte necrosis. In the intrahepatic bile ducts of all but one case, in the hepatic ducts and glands at the porta hepatis, and in the extrahepatic ducts where epithelium remained, there was degeneration of the epithelium and intramural inflammation. In the ducts at the porta hepatis and in six of eight extrahepatic ducts where epithelium remained, there was extensive mural fibrosis compromising the diameter of the duct lumens. Three cases showed the inflammatory changes distal to sites of closure of the extrahepatic ducts. These findings demonstrate that hepatitis, intrahepatic cholangitis, and sclerosing cholangitis of the extrahepatic ducts all interact to produce acquired obstruction to bile flow in biliary atresia.

4182 SONOGRAPHIC "PARALLEL CHANNEL" SIGN OF BILIARY TREE ENLARGEMENT IN MILD TO MODERATE OBSTRUCTIVE JAUNDICE. (Eng.) Conran, M. R.; Landay, M. J.; Janes, J. O. (Parkland Memorial Hosp., 5201 Harry Hines Blvd., Dallas, TX 75235). *Am. J. Roentgenol.* 130(2):279-286; 1978.

Minimal dilatations of the biliary system caused by obstruction were diagnosed by recognition of the "parallel channel" signs that are based on the concomitant imaging of the right and left main portal vein branch and the adjacent main hepatic duct. Eighty-six patients with jaundice or an elevation of the bilirubin level of less than 11.0 mg/100 ml were studied prospectively for 10 months. Ultrasound parallel channel signs were best demonstrated on transverse sections in the supine position. Each ultrasound diagnosis of dilated bile ducts was considered a true positive only when confirmed by surgery, percutaneous transhepatic cholangiography, or retrograde endoscopic cannulation. Obstructive jaundice was correctly diagnosed with the parallel channel sign in 27 patients. The lowest bilirubin value at which the sign was positive was 1.5 mg/100 ml. Nonobstructive jaundice was correctly diagnosed in 44 patients. There were three false-negative diagnoses in which the sign was not present despite obstruction and elevated bilirubin. There were no false-positive cases. Five case reports are presented, one of which demonstrated that, without parallel channel sonography, an incorrect diagnosis would have been made. Parallel channel sign is a simple method for the accurate differentiation between obstructive and nonobstructive jaundice when there is mild to moderate elevation of the bilirubin level.

4183 BILIARY PANCREATIC REFLUX DURING PEROPERATIVE RADIOMANOMETRY. (Eng.) Yvergneaux, J. P.; Bauwens, E.; Yvergneaux, E. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, June 8, 9, 1976.* (S. Karger: Basel): 80-85; 1977.

Peroperative transcystic radiomanometries of 100 gallbladder patients with strict, normal, manometry (no hypertony and no hypotony) and 424 patients without jaundice or malignant pathology of the biliary tree who had either normal, hypotonic, or hypertonic manometry were studied to analyze pancreatic reflux (WR). In the gallbladder patients, WR was more frequent in those over 60 yr ($p<0.005$) and increased in incidence with rising perfusion pressure, increasing flow rate, or occurrence of sphincter hypotony. There was a significant increase in the diameter of the duct of Wirsung with increasing age (from 2.2 ± 0.24 mm at <40 yr to 3.3 ± 0.23 mm at >60 yr, $p<0.001$). Only absence or congenital atrophy of the duct of Wirsung excluded WR. WR appears at minimal opening pressure ($p<0.001$) and quickly becomes total when the papillar channel is more developed than the infundibulum of the common bile duct or when the infundibulum of the common duct is undersized compared to the common channel. The most common anatomical channel joined at an acute angle by the two arms of the papilla, forming a "Y" figure, and WR appeared at a pressure higher than minimal. In the patients without jaundice or malignant pathology, WR is rarer in hypertony (37.5%) than in normotony and hypotony (52%, $p<0.025$); it appeared mostly during perfusion or marked hyperpression (72%, $p<0.005$). In residual pancreatitis, WR is short and never total. In benign Oddian stenosis, WR is rarer than normal (32%, $p<0.001$) and short, with a large Wirsungian caliber (4 ± 0.3 mm) that is significantly ($p<0.005$) larger than in patients of the same age with normal manometry. The results show that increased pressure on Wirsung's duct by physiologic (e.g., fatty meal) or pathologic (e.g., benign papillary stenosis) conditions may decrease WR.

4184 CHOLEDOCHODUODENOSTOMY AS AN ADJUNCT TO CHOLEDOCHOLITHOTOMY. (Eng.) Schein, C. J.; Shapiro, N.; Gliedman, M. L. (Albert Einstein Coll. Medicine, New York, NY). *Surg. Gynecol. Obstet.* 146(1):25-32; 1978.

The indications for and results of choledochoduodenostomy in 100 patients operated for calculus related disease of the common bile duct are reported. There were no significant early or late complications of the anastomotic procedure. The 3% mortality was related to antecedent advanced liver disease in two instances and, in one instance, to intra-abdominal sepsis. The surgical bypass had the advantage of circumventing the retained stone problem or the sequelae of benign obstructive disease in the distal part of the choledochus. It permits postoperative roentgenographic and endoscopic evaluation of the anastomotic site. Cholangitis, blind segment disability, and malfunction have not been seen with these indications and this technique. When the common bile duct is at least 1.4 cm wide, primary or secondary choledochoduodenostomy with a wide anastomosis has significant advantages over T-tube intubation in the therapeutic and prophylactic management of choledocholithiasis.

4185 ENDOSCOPIC PAPILLOTOMY. (Eng.) Koch, H.; Rosch, W.; Schaffner, O.; Demling, L. (Medizinische Universitatsklinik, Krankenhausstrasse 12, D-8520 Erlangen, W. Germany). *Gastroenterology* 73(6):1393-1396; 1977.

Experience with endoscopic electrosurgery in the treatment of common bile duct obstruction in 267 patients is reviewed. In 192 of 222 patients with choledocholithiasis, all calculi were evacuated by endoscopic papillotomy (EP). The remaining patients had EP because of papillary stenosis. Complications of EP included nine instances of pancreatitis, seven of bleeding, and two perforations. In 2 of 32 patients having EP for papillary stenosis, stenosis has reappeared on follow-up. The two fatalities were attributable to purulent cholangitis and acute bleeding. This complication rate is less than that reported for the traditional surgical procedures required to manage these situations. The endoscopic method requires less hospitalization and recuperation. EP and stone extraction are the methods of choice for managing common duct obstruction in high risk patients before cholecystectomy, for retained or reformed stones after cholecystectomy, and for papillary stenosis.

4186 ANAEROBES IN HUMAN BILIARY TRACTS. (Eng.) England, D. M.; Rosenblatt, J. E. (Wiesbaden U.S. Air Force Hosp., APO, New York, NY 09330). *J. Clin. Microbiol.* 6(5):494-498; 1977.

Aerobic and anaerobic microorganisms were studied in bile cultures from 371 patients who underwent biliary tract surgery during a 2-yr period. Sixty-nine percent of the cultures were positive, and 41% of these grew anaerobes, although they were present in pure culture only twice. Mixed cultures most commonly contained four different organisms (3 aerobes and 1 anaerobe). *Bacteroides fragilis* was the single most commonly isolated anaerobe and ranked fourth in terms of overall isolates behind *Escherichia coli*, group D streptococci, and *Klebsiella*. *B. fragilis* accounted for 7.0% of the total aerobic and anaerobic isolates and was present in 21% of all positive cultures. *Pseudomonas aeruginosa* and *Clostridium perfringens* ranked fifth and sixth, providing 6.5% and 5.9% of all isolates, resp. This study demonstrates the frequent presence of anaerobes in patients with bactibilia and suggests that these organisms be considered in the formulation of antimicrobial therapy for infections involving human biliary tracts.

4187 ELECTRON PROBE MICROANALYSIS IN THE STUDY OF GALLSTONES. (Eng.) Been, J. M.; Bills, P. M.; Lewis, D. (Dept. Chemical Physics, Univ. Surrey, Guildford, Surrey, England). *Gut* 18 (10):836-842; 1977.

The structure and composition of gallstones were studied using an electron probe microanalyzer in conjunction with other methods. Gallstones were studied layer by layer without greatly disturbing the arrangement of the materials present. Elements, including trace elements such as copper, iron, and manganese, were identified and their distributions mapped. The range of the method was extended to determine the character and distribution of certain chemical groups present by treating sections of gallstone with reagents that contained easily detected elements. The nature of the bonding of the sulfur in the stones was studied by examining the sulfur x-ray spectrum. Pigmented sulfur-containing deposits were found to contain sulfur in a low valence state, but taurine conjugates and the sulfate groups of mucosubstances were not detected. Microcrystalline apatite present in the stones contained some manganese and seemed to be implicated in the adsorption of the low valence sulfur compound and in the nucleation of some stones.

4188 THE REMOVAL OF RETAINED BILIARY TRACT STONES: REPORT OF 105 CASES. (Eng.) Garrow, D. G. (Vancouver General Hosp., Vancouver, British Columbia, Canada). *Br. J. Radiol.* 50(599): 777-782; 1977.

The results of treating 105 cases of retained biliary tract stones are reported. The removal of retained biliary stones was achieved by the use of a steerable catheter and wire basket after T-tube removal. Filling the T-tube tract with contrast after removal of the T-tube made introduction of the catheter much easier and reduced the hazard of tract perforation. Coating the wire Dormia basket with K-Y Jelly or silicone greatly reduced friction between the basket and the lumen of the Burhenne catheter used. In cases where there was doubt about the presence of stones or portions of stones within the duct system after an attempted removal, a urethral catheter was used to keep the tract open, and a cholangiogram was repeated in 48 hr. A total of 115 catheterizations were performed in the 105 patients, with 10% of the patients having more than one catheterization. There were six failures, six complications, and no deaths. Multiple stones were found in 27 patients, and 11 patients had only debris within the duct (no stone actually removed). The complications included rupture of the T-tube tract in two patients, cholangitis in three patients, and a large subhepatic bile collection 3 months after stone removal in one patient.

4189 FEASIBILITY OF LOW-DOSE AND INTERMITTENT CHENODEOXYCHOLIC ACID THERAPY OF GALLSTONES. (Eng.) Marks, J. W.; Bonorris, G. G.; Chung, A.; Coyne, M. J.; Okun, R.; Lachin, J. M.; *et al.* (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *Am. J. Dig. Dis.* 22(10):856-860; 1977.

The feasibility of low-dose and intermittent chenodeoxycholic acid therapy was assessed in 18 patients with gallstones by studying the induction and persistence of chenodeoxycholic acid-induced biliary lipid changes. Biliary lipid composition with each of three doses of chenodeoxycholic acid was determined in bile samples obtained by cholecystokinin-stimulated duodenal drainage before, after 1 week and 1 month of treatment, and up to 9 weeks after discontinuation of treatment. The lowest dose that significantly reduced the relative concentration of biliary cholesterol was 250 mg/day. A significant reduction occurred 1 week after initiation of treatment ($p<0.05$) and was maintained for 9 weeks following discontinuation of treatment. Thus, clinical trials of low-dose and intermittent chenodeoxycholic acid therapy for gallstone prophylaxis or dissolution are warranted.

4190 PRIMARY COMMON DUCT STONES. (Eng.) Saharia, P. C.; Zuidema, G. D.; Cameron,

J. L. *In: Transactions of the Southern Surgical Association Eighty-Eighth Annual Meeting Held at the Breakers, Palm Beach, Florida, December 6, 7, 8, 1976.* (Philadelphia: J. B. Lippincott Co.): 88: 101-105; 1977.

Clinical presentation, operative findings, surgical treatment, and long term follow-up results are reported in 30 patients with primary common duct stones. Criteria for diagnosis included at least a 2-yr symptom free interval following cholecystectomy; soft, light brown stones or sludge present in the common duct; and the absence of a long cystic duct remnant or a biliary stricture from the previous surgery. The average age of the patients was 66 yr. The interval between cholecystectomy and the diagnosis of primary common duct stones averaged 12 yr. Acute cholangitis was a frequent mode of presentation. At the time of surgery the bile duct was often dilated out of proportion to the serum bilirubin. In only 1 of the 30 patients was ampullary stenosis present. Twenty-six patients had only stone extraction and insertion of a T tube for treatment of their primary common duct stones. Twenty-two of the 26 were followed for an average of 4 yr and 9 months with no evidence of recurrent stones in 18. Four developed recurrent primary common duct stones 1, 5, 5, and 7 yr later. It is concluded that most patients with primary common duct stones do well after stone extraction alone.

4191 INFLUENCE OF CHOLIC AND CHENODEOXYCHOLIC ACID ON BILIARY CHOLESTEROL SECRETION IN MAN. (Eng.) Lindblad, L.; Lundholm, K.; Schersten, T. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Eur. J. Clin. Invest.* 7(5):383-388; 1977.

The interrelationships between biliary bile acid, lecithin, and cholesterol secretion rates were studied during depletion of the bile acid pool and during duodenal administration of cholic or chenodeoxycholic acid in 13 patients 7-12 days after operation for uncomplicated gallstone disease. The mean lecithin secretion rate was significantly higher during cholic acid than during chenodeoxycholic acid infusion (0.45 ± 0.03 versus 0.30 ± 0.03 μmol lecithin/μmol bile acid, $p<0.01$). The relationship between bile acid and cholesterol secretion rates was curvilinear during bile acid pool depletion and during duodenal cholic acid infusion, fitting an equation [$y=x/(a + bx)$] that is the same function found in Michaelis-Menten enzyme kinetics. At low bile acid secretion rates, during bile acid pool depletion and during cholic acid infusion, the lecithin secretion rate was significantly correlated ($r=0.80$, $r=0.70$, and $r=0.86$, resp.) to the cholesterol secretion rate. The bile acid and cholesterol secretion rates were not significantly correlated during chenodeoxycholic acid infusion. However, under this experimental condition, a significant ($r=0.50$) curvilinear relationship between lecithin and cholesterol secretion rates was found. The hepatic bile became unsaturated in cholesterol at significantly lower bile acid secretion rate during mainly chenodeoxycholic acid infusion (10.7 ± 0.3 μmol/min) than during mainly cholic acid infusion (15.6 ± 0.5 μmol/min, $p<0.001$).

4192 ELEVATIONS IN SKIN TISSUE LEVELS OF BILE ACIDS IN HUMAN CHOLESTASIS: RELATION TO SERUM LEVELS AND TO PRURITUS. (Eng.) Ghent, C. N.; Bloomer, J. R.; Klatskin, G. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 73(5):1125-1130; 1977.

To define the relationship of bile acid retention to the pruritus of cholestasis, individual bile acids in serum, in acetone swabs of skin, and in skin tissue were quantified in 13 patients with cholestasis undergoing laparotomy and in 8 controls. There was no consistent relationship between pruritus and concentrations of either total or individual bile acids in serum. Skin tissue concentrations of bile acids were elevated in patients with cholestasis, were linearly related to serum levels, and did not differentiate between those patients with and those without pruritus. Concentrations of bile acids on the skin surface, which were lower than those reported by others (2.7 ± 2.0, 4.5 ± 1.0, and 2.1 ± 1.0 μg/750 cm^2 for patients with pruritus and cholestasis, patients with cholestasis alone, and controls, resp.), did not correlate with pruritus and were decreased by simple soap and water washing. These data indicate that the pruritus of cholestasis is not directly related to the skin tissue concentration of any of the major bile acids, although a relationship to a particular molecular form of bile acids could not be excluded.

4193 UNCONJUGATED BILIRUBIN, AND THE HYDROLYSIS OF CONJUGATED BILIRUBIN, IN GALLBLADDER BILE OF PATIENTS WITH CHOLELITHIASIS. (Eng.) Boonyapisit, S. T.; Trotman, B. W.; Ostrow, J. D. (Siriraj Hosp., Mahidol Univ., Bangkok 7, Thailand). *Gastroenterology* 74(1):70-74; 1978.

To assess the role of hydrolysis of conjugated (CB) to unconjugated (UCB) bilirubin in pigment gallstone formation, 52 samples of human gallbladder bile were aspirated at laparotomy. In each bile sample, the concentrations of CB and UCB were determined, using a new thin layer chromatographic method, and the rate of hydrolysis of CB to UCB was measured during incubation at 37 C, performed under nitrogen and in the dark to prevent oxidation of the bile pigments. Nine control biles without gallstones contained no more than 1.87 mg/dl of UCB (<1.2% of total bilirubin), and showed no significant hydrolysis of CB to UCB. Among 24 biles containing cholesterol gallstones, only 3 showed significant hydrolysis of CB, and only 1 of these exhibited increased concentrations of UCB. By contrast, 10 of 19 biles containing pigment precipitates or gallstones revealed increased concentrations of UCB and/or significant hydrolysis of CB to UCB. Biles containing pigment calculi were best distinguished by their supersaturation with the poorly soluble, nonionized form of UCB at the measured bile acid concentration of each sample. Total bilirubin concentrations were not elevated except in four of the five biles containing pigment precipitates. Among 15 biles cultured both aerobically and anaerobically, only 2 grew any bacteria (*Escherichia coli*), and there was no relation between the presence of bacteria and hydrolysis of CB to UCB. It is concluded that some UCB is normally secreted into bile, and that hydrolysis of CB and excessive concentrations of UCB, especially its nonionized form, are associated with pigment gallstones, although related to factors other than bacterial infection.

4194 NON CALCULOUS CHOLECYSTITIS: AN 8 YEAR REVIEW OF CASES TREATED BY ELECTIVE CHOLECYSTECTOMY.

(Eng.) Jones, A. G.; Blair, D. W. (Royal Infirmary, Aberdeen, Scotland). *Scott. Med. J.* 23(1):27-31; 1978.

Thirty-six cases of acalculous cholecystitis (found in a total of 248 cases of cholecystectomy) are reviewed with regard to signs, symptoms, and radiological investigations. The patients had suffered discomfort that lasted from 5 days to 34 yr, and during this time 66 cholecystograms were performed in 32 of these subjects. Persistently negative x-ray examinations were observed in 18 patients, while poor function of the gallbladder was demonstrated in 10. Of 66 gallbladder visualizations, 4 showed stones; 3 of these were false positives, while one showed a common duct stone that was confirmed at operation. Of 42 barium examinations on 25 of the patients, 38 were negative, 2 showed hiatal hernia, 1 showed duodenal diverticula, and 1 showed paraesophageal hiatal hernia plus duodenal diverticula. Gallbladders of all patients with acalculous cholecystitis revealed some abnormalities at surgery. Histological examination showed chronic cholecystitis (7 cases), one being thick-walled with a rupture at the tip and pyogenic granulations. One showed chronic cholesterosis. The remainder showed variable degrees of chronic inflammation. The majority of specimens also had very thickened and, in some cases, fibrosed gallbladder walls. Nineteen patients had some postoperative complications, mainly chest (9) and urinary (8) tract infections, wound infection (6), and pneumonia (4). One 80-yr-old patient died of a pulmonary embolus. The majority of the patients (29) were symptomless within 2 months after surgery; in two other cases, symptoms disappeared in 5 and 12 months, resp. Four subjects had postoperative symptoms related to the pre-operative ones, and one had new symptoms. Patients with recurrent attacks of cholecystitis should be considered for cholecystectomy despite repeatedly negative radiological examinations.

4195 DIAGNOSIS AND MANAGEMENT OF POST-CHOLECYSTECTOMY SYMPTOMS: THE PLACE OF ENDOSCOPY AND RETROGRADE CHOLEDOCHOPANCREATOGRAPHY.

(Eng.) Blumgart, L. H.; Carachi, R.; Imrie, C. W.; Benjamin, I. S.; Duncan, J. G. (Glasgow Royal Infirmary, Glasgow, Scotland). *Br. J. Surg.* 64(11): 809-816; 1977.

The value of endoscopic retrograde choledochopancreatography (ERCP) in the diagnosis and management of postcholecystectomy symptoms was assessed in 52 patients symptomatic after cholecystectomy in whom barium meal studies and i.v. cholangiography had failed to yield a diagnosis. Cannulation of the papilla of Vater was carried out in 50 of the patients in a mean time of 10 min. Diagnostic information demonstrating a pathological lesion or a normal biliary and pancreatic ductal system was obtained by endoscopy and ERCP in 48 cases. There were no serious complications. A pathological lesion was demonstrated in all but one of the patients presenting with jaundice, cholangitis, or pancreatitis, but the diagnostic yield was not as high in patients with vague upper abdominal symptoms. Endoscopy and ERCP are the investigative procedures of choice in complex postcholecystectomy patients in whom i.v. cholangiography either fails, gives incomplete information, or is false-negative despite continuing symptoms or clinical evidence of residual biliary disease.

4196 MULTIPLE GALLBLADDERS.

(Eng.) Harlaftis, N.; Gray, S. W.; Skandalakis, J. E. (Emory Univ. Sch. Medicine, Atlanta, GA). *Surg. Gynecol. Obstet.* 745(6):928-934; 1977.

Two hundred seven reports in the literature of double gallbladder and eight of triple gallbladder are reviewed. Multiple gallbladders form a continuous spectrum of malformation, from an externally normal gallbladder with an internal longitudinal septum to the most widely separated accessory gallbladders. Although multiple gallbladders are found more frequently in women than in men, the authors believe that the duplication occurs about equally in men and women and that the difference is in the frequency of gallbladder disease and hence in the frequency of discovery of the anomaly. When disease is present, both organs are usually affected if they are intimately connected. When separation is complete and each organ has its own cystic duct, it is not unusual to find one healthy and one diseased gallbladder. Cholecystography remains the best means for preoperative diagnosis of multiple gallbladders, but it is most effective with healthy gallbladders. In about 69% of surgically confirmed instances of duplication, the preoperative cholecystogram failed to reveal the duplication. Hence, abnormal films are diagnostic, and normal films do not rule out duplication. Operative cholangiography should be used in all doubtful instances. Symptomatic multiple gallbladders require cholecystectomy. All cystic structures should be removed. In elderly or debilitated patients, cholecystostomy should be considered. Multiple gallbladders without symptoms should be left alone.

4197 JAUNDICE AND HEPATITIS B SURFACE ANTIGEN AND ANTIBODY IN GREEK HAEMOPHILIACS.

(Eng.) Yannitsiotis, A.; Bossinakou, I.; Louizou, K.; Panayotopoulou, C.; Mandalaki, T. (51 Homirou str., Athens, 135, Greece). *Scand. J. Haematol.* (Suppl. 30):11-15; 1977.

The incidence of hepatitis B surface antigen (HBsAg) and antibody (HBsAb), and of abnormal liver function, in 101 Greek multitransfused hemophiliacs with or without a previous history of jaundice was studied. Using the hemagglutination inhibition assay, HBsAg was detected in 9.9%, HBsAb in 61.3%, and HBsAg plus HBsAb in 11.8% of the patients. The incidence of jaundice was 14.8%. Liver function was tested by means of Normotest, SGOT, SGPT, and serum protein electrophoresis; abnormal values were found in 47% of the patients. The abnormal findings were related to the presence of HBsAg or HBsAb and to the history of jaundice. There was no significant difference between the various groups of patients.

4198 BILIARY BACTERIA AND HEPATIC HISTOPATHOLOGIC CHANGES IN GALLSTONE DISEASE. (Eng.)

Flinn, W. R.; Olson, D. F.; Oyasu, R.; Beal, J. M. *In: Transactions of the Southern Surgical Association Eighty-Eighth Annual Meeting held at the Breakers, Palm Beach, Florida, December 6, 7, 8, 1976.* (Philadelphia: J. B. Lippincott): 88:101-105; 1977.

The frequency and severity of liver damage in 126 patients with gallstone disease and the role of bacteria in the development of these changes were assessed. Needle biopsy of the liver demonstrated acute inflammation of portal triads in 19 of the patients with gallstones, a finding not present in the 26 control patients. Acute inflammation occurred more often in patients with acute cholecystitis and choledocholithiasis than in chronic cholecystitis. Cultures of the biliary tract or liver were positive in 23 of 64 patients. The frequency of positive bile cultures increased with the severity of the biliary tract disease. Five of six positive liver cultures were from patients with acute cholecystitis or choledocholithiasis. The data suggest that impairment of bile flow is responsible for the acute hepatic inflammatory changes.

4199 CHOLELITHIASIS AND WILSON DISEASE. (Eng.)

Rosenfield, N.; Grand, R. J.; Watkins, J. B.; Ballantine, T. V. N.; Levey, R. H. (Harvard Medical Sch., Boston, MA). *J. Pediatr.* 92(2):210-213; 1978.

Clinical data is presented on three children with Wilson's disease who had symptoms suggestive of cholecystitis as well as radiologic evidence of gallstones, which were subsequently proven at the time of laparotomy. The gallstones from the patients with Wilson's disease had an appreciably higher content of cholesterol than gallstones from age-matched children with hemolytic disease. Since gallstones may be present for years before they produce clinical symptoms, young patients with Wilson's disease should undergo routine investigation for the presence of stones; cholelithiasis should also be considered in the differential diagnosis of abdominal pain in such patients.

4200 SPHINCTEROTOMY OF ODDI'S SPHINCTER. (Eng.)

Mentouri, B. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, June 8, 9, 1976.* (S. Karger: Basel): 190-195; 1977.

To study the effectiveness of sphincterotomy of Oddi's sphincter as a treatment for lithiasis of the common bile duct (CBD), 483 sphincterotomies performed between 1963 and 1975 were studied. The sphincterotomies were indicated for reasons of necessity in 302 cases (impacted stone in 84, removal by upper route impossible in 130, odditis in 73, and pancreatitis plus impacted stone in 15) and for reasons of security (where the aim is to carry out internal drainage of the CBD) in 176 cases (multiple stones in 61, biliary deposit and cholangitis in 30, lithiasis with one stone in 72, and residual lithiasis in 13); in 5 cases, sphincterotomy was abusive, due to erroneous interpretation of the x-ray picture of the lower CBD. Morbidity concerning sphincterotomy occurred in 34 cases (postoperative pancreatitis, 14; duodenal fistula, 5; subphrenic abscess, 7; cholangitis, 3; hemorrhage, 5) and in 11 cases not connected with sphincterotomy for an overall morbidity rate of 9.2%. There were 21 deaths connected with sphincterotomy, due to acute postoperative pancreatitis (12), subphrenic abscesses (4), duodenal fistulas (2), cholangitis (2), and hemorrhage of sphincterotomy (1). Long-term results in 234 patients were excellent in 163, good in 27, fair in 41, and poor in 3. The study suggests that sphincterotomy is a satisfactory technique, especially with respect to the very few cases of retained stone (1/234). However, postoperative mortality due to pancreatic complications (55% of deaths) suggests that indications for sphincterotomy should be applied in a more eclectic manner.

4201 BENIGN STENOSIS OF THE PAPILLA OF VATER: DIAGNOSIS OF 119 CASES WITH CONVENTIONAL AND SELECTIVE LOW RADIOMANOMETRY. (Eng.)

Yvergneaux, J. P.; Bauwens, E.; Outryve, L. V.; Yvergneaux, E. (President Rooseveltlaan 92, B-9000 Ghent, Belgium). *Acta Chir. Belg.* 76(6):523-532; 1977.

Experience with intraoperative radiomanometry with serial conventional films (panoramic cholangiography) and intra-abdominally placed large dental films (selective low cholangiography) in 2,095 patients with benign biliary pathology is presented. These techniques revealed 119 cases of stenosis of the papilla of which 34 were detected during secondary operations on 85 patients. With this procedure, a clear definition of benign stenosis of the papilla was obtained. The features included: moderate hypertony, disappearance of the normal rhythmical sphincter activity, widening of the biliary infundibulum so that it was wider than the intrapancreatic part of the common bile duct above it, rarity of biliary pancreatic reflux, and enlargement of the pancreatic duct. These signs are characteristic of chronic stasis in both the common bile duct and the pancreatic duct, from the infundibulum to the intrahepatic ducts above the stenotic papilla.

GENERAL

4231 EFFECTS OF INTERMITTENT AND CONTINUOUS FEEDING ON BILIARY LIPID SECRETION IN MAN. (Eng.) von Bergmann, K.; Mok, H. Y. I.; Grundy, S. M. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting, Basel, Switzerland, 11-12 October, 1976.* (Baltimore, Md.: University Park Press): 191-196; 1977.

The effects of continuous versus intermittent feeding was compared by measuring hourly outputs of biliary lipids in 9 patients and by determining bile acid and cholesterol absorption in 23 and 28 patients, resp. The determinations were made in both obese and nonobese patients, in some with mild hyperlipidemia, and in three with alcoholic cirrhosis. Biliary lipid output, measured in mg/hr, was very similar for continuous and intermittent feeding (cholesterol, 46 and 48, resp.; bile acids, 769 and 794, resp.; phospholipids, 308 and 304, resp.). Total bile acid absorption by the intestine in all subjects was 97.5%. There were no significant differences among the various types of patients. Cholesterol absorption was 60%, with no significant differences for the different groups. These findings indicate that similar results are obtained for average hourly secretion rates of biliary lipids whether the diet is given continuously into the duodenum or is fed p.o. as three meals a day. Thus, studies carried out by the two methods should be comparable, provided other aspects in the methodology of intestinal perfusion are similar.

4232 HEPATIC BILIRUBIN UDP-GLUCURONYLTRANSFERASE IN PATIENTS WITH SICKLE CELL ANEMIA. (Eng.) Maddrey, W. C.; Cukier, J. O.; Maglalang, A. C.; Boitnott, J. K.; Odell, G. B. (Johns Hopkins Hosp., 601 N. Broadway, Baltimore, MD 21205). *Gastroenterology* 74(2, Part 1):193-195; 1978.

To determine the effects of the excessive bilirubin load in sickle cell anemia on the microsomal conjugating enzyme, hepatic bilirubin uridine diphosphate (UDP) glucuronyltransferase, levels of this enzyme were measured in liver biopsies from 14 patients with sickle cell anemia and 14 control patients with modest elevations in the levels of serum transaminases or alkaline phosphatase, 10 controls who were chronic drug users, 6 patients with Gilbert's syndrome, and 2 patients with hereditary spherocytosis. UDP-glucuronyltransferase activity in the patients with sickle cell anemia was twofold greater ($p<0.005$) than in the 14 nonjaundiced control patients. The elevated UDP-glucuronyltransferase activity in sickle cell anemia was similar to that found in the 10 patients who chronically ingested drugs (barbiturates or estrogens) known to increase UDP-glucuronyltransferase activity. These observations suggest that enhanced conjugation of bilirubin in patients with sickle cell anemia may result from substrate (bilirubin) induction of UDP-glucuronyltransferase.

4233 DAILY URINARY CATECHOLAMINE PROFILE IN MARASMUS AND KWASHIORKOR. (Eng.) Ramirez, A.; Fletes, L.; Mizrahi, L.; Parra, A. (Centro Medico Nacional, Instituto Mexicano del Seguro Social, Mexico City, Mexico). *Am. J. Clin. Nutr.* 31(1):41-45; 1978.

Studies were carried out to determine the daily urinary excretion of catecholamines in normal weight children and in children with protein-calorie malnutrition, as part of a comprehensive study to evaluate the relationships between altered energy metabolism and the hormonal adaptations present in these conditions. In eight normal weight infants (mean age 7.3 months) with gram-positive gastrointestinal or pulmonary infections, 24-hr urine collections were performed on two consecutive days, and triplicate determinations of total catecholamines, dopamine, norepinephrine, epinephrine, and vanilmandelic acid were performed on each urine sample. These results were compared to those obtained in 4 severely marasmic infants (mean age 4.5 months) with moderate hypovolemic shock, 10 severely marasmic infants (mean age 6.4 months) without shock, and 6 children with acute kwashiorkor (mean age 20.6 months). All patients had the same type of infection as the normal weight infants. The day-to-day variability in urinary catecholamine excretion was not significant in any of the groups studied. Marasmic infants and children with kwashiorkor excreted similar amounts of total catecholamines as normal weight infants. However, marasmic and normal weight infants excreted proportionally three to four times less epinephrine than norepinephrine. Children with kwashiorkor excreted similar amounts of the two hormones (epinephrine:norepinephrine ratio=0.88). These findings suggest that in marasmus and kwashiorkor, norepinephrine and epinephrine, resp., are involved in the regulation of the metabolic adaptations to these diseases.

4234 PANCREATIC VEIN CATHETERIZATION WITH GASTRIN ASSAY IN NORMAL PATIENTS AND IN PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Ingemansson, S.; Larsson, L. I.; Lunderquist, A.; Stadil, F. (Dept. Surgery, Univ. Lund, 5-221 85 Lund, Sweden). *Am. J. Surg.* 134(5): 558-563; 1977.

Simultaneous catheterization of the aorta and the caval, portal, and pancreatic veins with blood sampling for gastrin radioimmunoassay was performed in three patients with the Zollinger-Ellison (ZE) syndrome and in five control patients without peptic ulcer disease to determine whether these procedures could be carried out in the patients with the ZE syndrome before and after tumor extirpation and total gastrectomy. In addition, the use of high pancreatic arteriovenous gastrin differences for the localization of gastrin-producing tumors was investigated. In the controls, the gastrin concentrations in the pancreatic veins ranged from 15 to 148 pg/ml (mean, 65; median, 67). Pre- and postoperative catheterizations were performed in two of the ZE patients, and very high gastrin concentrations in several pancreatic veins indicated the occurrence of multiple tumors, whereas angiography revealed only one tumor in one of the patients. Twelve months after extirpation of the tumors and total gastrectomy, gastrin concentrations in peripheral as well as pancreatic venous blood were lower ($p<0.001$) but still pathologically high. The third patient was catheterized 2 and 12 months after tumor extirpation and total gastrectomy; the gastrin values were within the range of the reference group (<100 pg/ml) except for one pancreatic vein with slightly increased concentrations. The gastrin concentration did not increase in the interval between the two catheterizations. No complications were noted. The triple catheterization technique with blood sampling for hormone assay is advocated as a diagnostic tool and as a localization procedure in patients with suspected or proved ZE syndrome.

4268 HYDATID DISEASE SCREENING: SANPETE COUNTY, UTAH, 1971-1976. (Eng.) Barbour, A. G.; Everett, J. R.; Andersen, F. L.; Nichols, C. R.; Fukushima, T.; Kagan, I. G. (Univ. Utah Medical Center, Salt Lake City, UT 84132). *Am. J. Trop. Med. Hyg.* 27(1):94-100; 1978.

Between 1971 and 1976, approximately 20% (2,265) of the population of Sanpete County, Utah, was screened for hydatid disease (*Echinococcus granulosus*) by intradermal, indirect hemagglutination and bentonite flocculation tests. In addition, dogs owned by the persons tested were purged with arecoline hydrobromide and the stool mucus was examined for cestodes. Of 34 persons who had follow-up chest radiographs and radioisotope liver scans, 6 were found to have asymptomatic hepatic cysts. If a participant who had pulmonary cysts and negative screening tests was included, the prevalence of asymptomatic hydatid disease would be 3/1,000. During the same period, 82 of 553 dogs successfully purged and examined had *E. granulosus* infections. Human cyst carriage was associated with dog ownership, particularly of infected dogs or in conjunction with sheep raising as the main livelihood. Combinations of immunodiagnostic tests were more efficacious in identifying cyst carriers than the tests used singly. Limitation of screening to high-risk groups (e.g., sheep raisers with dogs) can reduce costs without reducing yield. Optimum management of the cyst carrier awaits further information on the natural history of asymptomatic hydatid disease.

GENERAL

Regional Enteritis

4278 BILE ACID STUDIES IN UNCOMPLICATED CROHN'S DISEASE. (Eng.) Vantrappen, G.; Ghoos, Y.; Rutgeerts, P.; Janssens, J. (Dept. Medical Res., Univ. Leuven, Leuven, B-3000, Belgium). *Gut* 18(9): 730-735; 1977.

Bile acid composition and pool size were studied in 13 unoperated patients with uncomplicated Crohn's disease (CD), 10 patients with ulcerative colitis (UC), and 10 normal subjects to determine the disorders of bile acid metabolism that are associated with the disease process itself. The bile acid pool size of the CD patients was significantly reduced (1.48 ± 0.16 g) as compared with the normal subjects (3.09 ± 0.27 g, $p<0.001$) and UC patients 2.92 ± 0.40 g, $p<0.01$). A significantly increased ($p<0.02$) amount of ursodeoxycholic acid (6.60 ± 1.93%) was found in the bile of many CD patients as compared with normal subjects (1.39 ± 0.12%) and UC patients (0.72 ± 0.34%). The ratio of glycine to taurine conjugates was greater in Crohn's disease than in normal subjects (5.15 ± 0.39 and 2.35 ± 0.17, resp.; $p<0.001$) or in UC patients (2.22 ± 0.27). Unconjugated bile acids constituted 4.64 ± 1.64% of the pool in CD patients, 2.59 ± 1.17% in normal subjects, and 7.02 ± 2.70% in UC patients.

Both the ESR and the serum cholesterol level correlated with the activity of the disease ($p<0.01$ and $p<0.05$, resp.). However, the parameter that correlated best with the activity index was the bile acid pool size ($p<0.001$): the more active the disease, the smaller the pool size. The latter finding suggests that the intestinal segment in which bile acid absorption is impaired in CD patients is much more extensive than the lesions demonstrated by radiological examinations.

4279 AMYLOIDOSIS AND CROHN'S DISEASE. (Eng.) Fausa, O.; Nygaard, K.; Elgjo, K. (Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 12(6):657-662; 1977.

Clinical findings in 7 patients with amyloidosis who were found among 85 patients subjected to intestinal resection for Crohn's disease between 1962 and 1974 are presented. Most patients had symptoms of inflammatory bowel disease of relatively short duration before amyloidosis was diagnosed and were without suppurative complications. Systemic involvement was seen in six patients. One died postoperatively from renal failure, and in two other patients, kidney transplantation was performed because of deterioration of a pre-existent renal insufficiency. Six patients were alive 6 months to 10 yr after amyloidosis was diagnosed. There is great risk of rapid deterioration of kidney function postoperatively in these patients. However, the authors' experiences suggest that in some cases the progression of amyloidosis may be delayed or prevented after surgical treatment of Crohn's disease.

4280 PYODERMA GANGRENOSUM COMPLICATING CROHN'S DISEASE. (Eng.) Korelitz, B. I.; Sommers, S. C. (Dept. Medicine, Lenox Hill Hosp., 100 E. 77th St., New York, NY 10021). *Am. J. Gastroenterol.* 68(2):171-176; 1977.

The 10-yr course of a woman (8-18 yr) with pyoderma gangrenosum complicating Crohn's disease is reported because of its rarity. The development of the skin lesions, their association with the inflammatory bowel disease, and their treatment are discussed. At age 8, the patient had an onset of abdominal cramps, fever, anorexia, and loose nonbloody stools. A barium enema showed narrowing and loss of haustrations in the transverse colon, more marked distally, with eccentric involvement of the circumference and pseudodiverticula formation. At age 11, skin eruptions developed on the extremities, flanks, and groin, characterized by clear drops with red halos suggesting pustules or infected erythema nodosum. At age 15, she had loose stools and recurrent skin lesions, two of which were only 4-5 mm across but looked like pyoderma gangrenosum. At age 18, she had recurrent nausea, chills, and loose stools accompanied by multiple round punched out ulcerations of the skin (1-5 mm in diameter). The patient was always treated with ACTH followed by prednisone plus maintenance therapy with salicylazosulfapyridine. Experience with pyoderma gangrenosum found in the literature is summarized. The treatment of pyoderma gangrenosum is the treatment of the underlying inflammatory bowel disease. High-dose steroid therapy led to remission of the disease, and the salicylazosulfapyridine prevented recurrences.

4281 COLONIC-DUODENAL FISTULA IN CROHN'S DISEASE. (Eng.) Korelitz, B. I. (45 E. 85 St., New York, NY 10028). *Am. J. Dig. Dis.* 22(12): 1040-1048; 1977.

Clinical and radiological findings in four cases of colonic-duodenal fistula complicating Crohn's disease are presented. In three instances, the fistula served as an indication for surgical intervention. After ileosigmoidostomy, ileorectal anastomosis, and ileostomy alone, the patients improved clinically but x-ray evidence of patency of the fistula persisted. Recurrent activity of the Crohn's disease in two patients responded to medical treatment, as it did in one patient without surgery at all. The internal fistula need not be a serious complication of Crohn's disease and should not serve as an indication for surgical correction for its own sake.

4282 CROHN'S DISEASE: STUDY OF 20 CASES. (Spa.) Daza Coronado, A.; Diaz Oller, J.; Dominguez D.-Adame, J.; Donado S. de Leon, J. L.; De Los Santos, D. (Ciudad Sanitaria "Virgen del Rocio," Residencia "Garcia Morato," Seville, Spain). *Rev. Esp. Enferm. Apar. Dig.* 50(2):139-148; 1977.

4283 SYMPOSIUM ON "CROHN'S DISEASE IN GALICIA, SPAIN." (Spa.) Fiol, M.; Ruiz Ochoa, V.; Portela Perez, D.; Gonzalez Abraldes, R.; Potel Lesquereux, J.; Perez Villanueva, J. (Hospital General de Galicia-Santiago, Galicia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 50(4):469-482; 1977.

4284 FREE PERFORATION IN CROHN'S DISEASE [Abstract]. (Eng.) Katz, S.; Katzka, I.; Platt, N. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY). *Gastroenterology* 72(5, Part 2):1078; 1977.

4285 ZINC DEFICIENCY: A COMPLICATION OF CROHN'S DISEASE [Abstract]. (Eng.) McClain, C. J. (Veterans Admin. Hosp., Minneapolis, MN). *Gastroenterology* 72(5, Part 2):1099; 1977.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

4286 THE LIGHT AND ELECTRON MICROSCOPIC DISTRIBUTION OF ACID PHOSPHATASE ACTIVITY IN HUMAN NORMAL OESOPHAGEAL EPITHELIUM. (Eng.) Hopwood, D.; Logan, K. R.; Milne, G. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Histochem. J.* 10(2):159-170; 1978.

The fine structural localization of acid phosphatase (AcPase) activity in human normal esophageal epithelium obtained by biopsy was studied with light and electron microscopy to determine whether it conforms to the general cellular pattern reported for other animals, if the membrane-coating granules are AcPase-positive, and if the distribution of activity helps explain the function of the granules in the esophagus. The highest activity was seen in the prickle cell layer merging into the lower functional layer. Electron microscopy revealed activity to be localized in GERL (the specialized region of the endoplasmic reticulum associated with the Golgi apparatus, which shows hydrolase activity that is also present in lysosomes), lysosomes, and membrane-coating granules, which probably secrete their contents into the intercellular space in the central part of the functional layer. AcPase activity is shown to correspond in its distribution to that found in other animal tissues. It is hypothesized that the membrane-coating granules play a role in the freeing of superficial cells for sloughing and the restriction of fluid loss between the cells.

4287 INFLUENCE OF STARVING ON THE RAT GASTRIC MUCOSA: LIGHT AND ELECTRON MICROSCOPICAL FINDINGS. (Eng.) Zaviacic, M.; Brozman, M.; Jakubovsky, J. (Medical Sch., Komensky Univ. Bratislava, Sasinkova 4, 80100 Bratislava, Czechoslovakia). *Exp. Pathol. (Jena)* 14(3/4):122-130; 1977.

The histology and ultrastructure of the rat gastric mucosa were investigated after 24, 48, 72, 144, and 168 hr of starvation. An increased desquamation of individual foveolar cells was found. In the preserved cells of the foveolae, the content of PAS-positive mucosubstances did not change during starvation, and no ultrastructural changes took place in the appearance or in the amount of the mucous granules. The number of lipid droplets increased in the mucous foveolar cells within 24 and 48 hr. During starvation, the mitochondria (mainly in the parietal cells) were enlarged and contained rare mitochondrial cristae. Some mitochondria were disintegrated and removed by lysosomes. The number of lysosomes (mainly cytosegresomes) was markedly increased in the parietal cells. A collapse of the intracellular canaliculi occurred, and the tubulovesicular profiles were narrowed. In chief cells, the profiles of the granular endoplasmic reticulum and Golgi apparatus were reduced. The ultrastructural changes induced by starvation can be interpreted functionally in changed histochemical parameters of the gastric mucosa.

4288 GASTRIC AND DUODENAL MUCOSA IN 'HEALTHY' INDIVIDUALS: AN ENDOSCOPIC AND HISTOPATHOLOGICAL STUDY OF 50 VOLUNTEERS. (Eng.) Kreuning, J.; Bosman, F. T.; Kuiper, G.; Lindeman, J. (Univ. Medical Center, Wassenaarseweg 62, Leiden, Netherlands). *J. Clin. Pathol.* 31(1):69-77; 1978.

To gain information on the variation in appearance of normal gastric and duodenal mucosa, and to determine the density of cellular infiltrate in the lamina propria and the relative numbers of different immunoglobulin-producing plasma cells, biopsy specimens from 50 volunteers without a clinical history of gastrointestinal disease were examined histologically and immunohistochemically. The antrum and fundus were normal in 32 of the 50 subjects, but the other 18 showed histopathological evidence of gastritis in either the antrum or fundus. The latter entity appeared to be age-related: 4, 4, 8, and 2 patients were in the age-groups 20-29, 30-39, 40-49, and 50-59, resp. Moderate to severe atrophy occurred in one patient in the 30-39 age group, four patients in the 40-49 age group, and one patient in the 50-59 age group. There was considerable variation in the appearance of the surface epithelium of the duodenum within and among individual subjects. Superficial gastric metaplasia in one or more biopsy specimens from the duodenal bulb was found in 64% of the individuals. Histopathological examination revealed signs of chronic inflammation in 12% of the subjects. In two cases, there was active inflammation but in only one of these was the diagnosis made on endoscopic appearances. Brunner's glands were found above the muscularis mucosae in 48 subjects, and in only 17 subjects were they present in the descending part of the duodenum. The number of plasma cells in different biopsy specimens from subjects not showing histological signs of inflammation was variable. The ratio IgA:IgG:IgM-producing plasma cells was constant from subject to subject as well as from specimen to specimen. The average ratio IgA:IgG:IgM was 10:2.4:1.1. This study reveals that histological evidence of severe gastritis or severe duodenitis may exist without clinical symptoms. It also shows that the normal duodenal mucosa may show considerable morphological variation.

4289 ACUTE AND CHRONIC EFFECTS OF 1,2 DIMETHYLHYDRAZINE IN MOUSE LARGE BOWEL MUCOSA [Abstract]. (Eng.) Deschner, E. (Memorial Sloan-Kettering Cancer Center, New York, NY). *Gastroenterology* 72(5, Part 2):1048; 1977.

4290 EVIDENCE FOR A NON-SYMMETRICAL ORIENTATION OF VAGAL EFFERENT FIBERS [Abstract]. (Eng.) Innes, D. L.; Martin, J. S.; Lang, I.; Tansy, M. F. (Temple Univ. Health Science Center, Philadelphia, PA 19140). *Fed. Proc.* 36(3):462; 1977.

ABSORPTION - EXCRETION - TRANSPORT

4295 EXPERIMENTAL STUDIES ON FLUID PATHOPHYSIOLOGY IN SMALL INTESTINAL OBSTRUCTION IN THE RAT. I. EFFECTS OF INTRALUMINAL HYPEROSMOLALITY. (Eng.) Johnson, L.; Nordstrom, H.; Nylander, G. (Karolinska Hosp., 104 01 Stockholm, Sweden). *Scand. J. Gastroenterol.* 13(1):49-56; 1978.

An experimental model was constructed using male albino Sprague-Dawley rats with an extraperitonealized 50-cm loop of the distal ileum to study the transfer of fluids to the intestinal lumen associated with ileus and its relationship to other factors such as parenteral administration of fluids. When 3 ml of a hyperosmolal glucose solution (1,600 mOsm/kg) were introduced into the empty loop, the intestinal mucosa functioned as a semipermeable membrane and permitted only fluids of low osmolality to enter the intestinal lumen, thus tending to normalize its hyperosmolal contents. The initial fluid volume was increased continuously by dilution and had tripled after 1 hr. The process of dilution followed a simple dilution curve. The osmolality of the intestinal fluid decreased rapidly and inversely to the increase in volume, being one-third the original osmolality after 1 hr and one-fourth the original after 2 hr. The intraluminal pressure increased steadily to 35 mm H_2O at the end of the 2-hr experiment, yet the transfer of fluid into the lumen continued for the whole experimental period, indicating increased smooth muscle tone probably due to hyperosmolal provocation. At the same time, hemoconcentration and serum osmolality both increased, reflecting the mobilization of fluids from the extravascular (80% of total mobilized) and vascular compartments. The continued accumulation of fluid in the intestinal lumen at a constant rate conflicts with the idea that pressure has an effect on the amount of fluid that accumulates.

4296 THE RELATIONSHIP BETWEEN VITAMIN D-STIMULATED CALCIUM TRANSPORT AND INTESTINAL CALCIUM-BINDING PROTEIN IN THE CHICKEN. (Eng.) Spencer, R.; Charman, M.; Wilson, P. W.; Lawson, E. M. (Univ. Cambridge and Medical Res. Council, Milton Rd., Cambridge CB4 1XJ, England). *Biochem. J.* 170(1):93-101; 1978.

The rapid stimulation of intestinal Ca^{2+} transport observed in vitamin D-deficient chicks administered 1,25-dihydroxycholecalciferol prompted a re-evaluation of the correlation previously observed between this stimulation and the induction of calcium-binding protein synthesis. By 1 hr after a dose of 125 ng of 1,25-dihydroxycholecalciferol, Ca^{2+} transport was increased. This increase occurred at least 2 hr before calcium-binding protein was detected immunologically and 1 hr before synthesis of the protein began on polyribosomes; thus, the hormone stimulates Ca^{2+} transport before calcium-binding protein biosynthesis is induced. The maximum increase in Ca^{2+} transport observed after this dose of 1,25-dihydroxycholecalciferol (attained by 8 hr) was similar to that observed after 1.25-25 μg of cholecalciferol, but the stimulation was only short-lived, in contrast with the effect observed after the vitamin was given. Later, after hormone administration, when Ca^{2+} transport had declined to its basal rate, the cellular content of calcium-binding protein remained elevated. Calcium-binding protein was synthesized on free rather than on membrane-bound polyribosomes, which implies that it is an intracellular protein. Rachitic chicks required the presence of dietary calcium for maximum stimulation of calcium-binding protein production by cholecalciferol. These results suggest that calcium-binding protein is an intracellular protein, and that its synthesis may be a consequence of the raised intracellular calcium content of the intestinal epithelial cells resulting from 1,25-dihydroxycholecalciferol-stimulated Ca^{2+} transport. It is proposed that calcium-binding-protein synthesis is necessary for maintaining the stimulated rate of Ca^{2+} transport, which is initiated by other factors.

4297 INTESTINAL TRANSPORT OF WEAK ELECTROLYTES: DETERMINANTS OF INFLUX AT THE LUMINAL SURFACE. (Eng.) Jackson, M. J.; Williamson, A. M.; Dombrowski, W. A.; Garner, D. E. (George Washington Univ. Medical Center, Washington, DC 20037). *J. Gen. Physiol.* 71(3):301-327; 1978.

The possibility that the intestinal transport of weak electrolytes is influenced by a region of distinctive pH at the luminal surface of the epithelial cell layer was examined using intestinal segments from male Wistar rats. The intestinal segments were exposed to various weak electrolytes (15 weak acids and 6 weak bases) in influx chambers. The uptake observed during the 1-min exposure period represented a unidirectional flux that was not complicated by a significant backflux. The determinants of weak electrolyte influx could be described mathematically in terms of the resistance of the unstirred layer to movement from the bulk phase to the cell surface, the degree of ionization of the weak electrolyte at the cell surface, and the cellular permeability to the nonionized weak electrolyte. The unstirred layer was totally rate-limiting in the cases of some poorly ionized or highly permeant compounds but not for most of the compounds studied. The experiments suggest that the pH value that influences weak electrolyte influx into intestinal epithelial cells is equal to the pH in the mucosal fluid bulk phase and do not provide support for the concept of a superficial region of distinctive pH as a significant determinant of weak electrolyte influx.

4298 COMPARATIVE INTESTINAL AND COLONIC ABSORPTION OF [4-^{14}C]CHOLESTEROL IN THE RAT. (Eng.) Roy, T.; Treadwell, C. R.; Vahouny, G. V. (George Washington Univ. Sch. Medicine and Health Sciences, Washington, DC 20037). *Lipids* 13 (1):99-101; 1978.

To determine whether sterols are significantly absorbed by the colon, the absorption of [4-^{14}C]cholesterol was compared in the duodenum and in the cecum of rats. [4-^{14}C]Cholesterol was administered as an aqueous emulsion with triolein and dry non-fat milk either directly into the upper duodenum or into the ileocecal junction of lymph duct cannulated rats. Lymph flow rates were similar in the two groups of animals. Whereas approximately 53% of the administered tracer dose of cholesterol was absorbed when introduced into the upper small intestine, only 0.06% appeared in lymph when administered into the cecum. Furthermore, less than 0.01% of the administered isotope was detected in urine and blood. These data demonstrate that the large intestine does not contribute significantly to the absorption of exogenous cholesterol in the rat.

4299 EFFECT OF ENZYME-INDUCING AND ENZYME-INHIBITING AGENTS ON DRUG ABSORPTION I: 3-O-METHYLGLUCOSE TRANSPORT IN RATS. (Eng.) Ravis, W. R.; Feldman, S. (Dept. Pharmaceutics, Univ. Houston, Houston, TX 77004). *J. Pharm. Sci.* 67(2):245-248; 1978.

The influence of pre-administration of phenobarbital, benzo[*a*]pyrene, or proadifen hydrochloride on 3-*O*-methylglucose transfer across the everted rat small intestine was examined. The active and passive components of the sugar transport mechanism were evaluated using 0.08 mM phlorizin, a potent inhibitor of active transport of sugars. Pretreatment of the animals with phenobarbital (80 mg/kg, i.p. or p.o. for 3 consecutive days) did not alter 3-*O*-methylglucose transfer characteristics. Pretreatment with i.p. administered benzo[*a*]pyrene (20 mg/kg) increased mucosal to serosal transfer of the sugar at low (0.1 mM) sugar concentrations. Enhancement of the active transfer of 3-*O*-methylglucose by pretreatment with proadifen hydrochloride (100 mg/kg, i.p. or p.o.) was noted at low sugar concentrations. The passive transfer of the sugar was reduced after pretreatment with proadifen hydrochloride. The situation in treated animals is complex and requires further study before a conclusion can be reached.

MOTILITY

4307 MANOMETRY AND ELECTROMYOGRAPHY OF THE UPPER ESOPHAGEAL SPHINCTER IN THE OPOSSUM. (Eng.) Asoh, R.; Goyal, R. K. (Univ. Texas Southwestern Medical Sch., 5323 Harry Hines Blvd., Dallas, TX 75235). *Gastroenterology* 74(3):514-520; 1978.

Studies were performed in anesthetized and conscious opossums to define the genesis of resting pressure and opening of the upper esophageal sphincter. Intraluminal pressures were measured with low compliance, perfused catheters. Electromyograms were recorded using miniature concentric bipolar electrodes from the cricopharyngeus, inferior pharyngeal constrictor, middle pharyngeal constrictor, proximal end of the esophagus, and geniohyoid muscles. Upper esophageal sphincter pressure showed radial as well as axial asymmetry; the pressures were higher in conscious than in anesthetized animals. Electromyographically, only the cricopharyngeus and inferior pharyngeal constrictor fired continuously at rest and ceased to fire during swallowing. *d*-Tubocurarine or section of the motor nerve abolished electrical activity in the cricopharyngeus and inferior pharyngeal constrictor and caused marked reduction but not obliteration of upper esophageal sphincter pressure. Contraction of the geniohyoid muscle abolished the remaining pressure in the upper esophageal sphincter. Moreover, contraction of the geniohyoid muscle caused a fall in upper esophageal sphincter pressure, even when the cricopharyngeus and inferior pharyngeal constrictor were kept contracted. These studies indicate that (1) the upper esophageal sphincter corresponds mainly to the cricopharyngeus and inferior pharyngeal constrictor, (2) the resting upper esophageal sphincter pressure is attributable to continuous active muscle contraction as well as to the elasticity of the surrounding structures, and (3) the opening of the upper esophageal sphincter is attributable to the inhibition of the contraction of the cricopharyngeus and inferior pharyngeal constrictor and the forward displacement of the larynx by the geniohyoid muscle.

4308 OESOPHAGEAL PERISTALSIS. A SIMPLE SYSTEM FOR THE RECORDING OF OESOPHAGEAL PERISTALSIS, AND THE INFLUENCE OF BOLUS VOLUME ON PEAK PERISTALTIC PRESSURE AMPLITUDE. (Eng.) Boesby, S.; Sondergaard, E. Y.; Madsen, T. (Odense Sygehus, Sdr. Boulevard 29, DK-5000, Odense C, Denmark). *Scand. J. Gastroenterol.* 13(2):149-153; 1978.

To simplify and improve esophageal pressure recordings and to determine the influence of dry and wet swallows of different bolus volumes on recorded pressure amplitudes, the peak esophageal peristaltic pressure amplitude was recorded in eight healthy subjects at points 5-cm and 15-cm proximal to the gastroesophageal sphincter by using an *in situ* tip-transducer simultaneously with a continuous flush perfused catheter system with external pressure transducer. Dry swallows and wet swallows of 2.5, 5, or 10 ml were made in random succession, three of each at 30-sec intervals. The mean peak esophageal peristaltic pressure amplitudes (in mm Hg) recorded by the *in situ* tip transducer at the 5-cm and 15-cm points, resp., were 34 and 30 (dry swallow), 56 and 45 (2.5-ml bolus), 54 and 49 (5-ml bolus), and 65 and 45 (10-ml bolus). The mean peak pressure amplitudes (in mm Hg) recorded by the perfused catheter at the 5-cm and 15-cm points, resp., were 31 and 26 (dry swallow), 53 and 43 (2.5-ml bolus), 51 and 46 (5-ml bolus), and 55 and 41 (10-ml bolus). In all cases, the pressures recorded by either system correlated well, and the peristaltic pressure amplitude was significantly higher ($p<0.10$) after the wet swallows. In addition, the difference in bolus volumes did not influence the peristaltic pressure amplitude. A possible explanation for the difference between pressures after wet and dry swallows is that, as a result of the distention caused by passage of the bolus, the length-tension characteristics become more optimal for the functioning of the esophageal musculature than is the case after a dry swallow. In conclusion, the simple catheter and flow system used in this study permits recording of peristaltic pressures independent of the shape of the transducer, and it is therefore well-suited for measuring esophageal contractions.

4309 EFFECT OF GASTRIC ANTRUM ON REGULATION OF LOWER ESOPHAGEAL SPHINCTER PRESSURE IN THE DOG.

(Eng.) Koelz, H. R.; Hollinger, A. P.; Sauberli, H.; Largiader, F.; Siewert, R.; Blum, A. L. (Kantonsspital, Univ. Zurich, Zurich, Switzerland). *Am. J. Physiol.* 234(2):E157-E161; 1978.

The role of the antrum in the regulation of lower esophageal sphincter pressure (LESP) was investigated in three unrestrained dogs equipped with Komarov-type esophagostomy, innervated antral pouch, and gastrojejunostomy. The integrity of the antrum was shown by gastrin release after 20% peptone perfusion of the antrum and after the i.v. injection of insulin (0.4 U/kg). The ability of the lower esophageal sphincter to respond to known stimuli was demonstrated by a dose-dependent rise of LESP after i.v. pentagastrin. Peptone instillation into the main stomach raised LESP from the basal 18.6 ± 1.8 to a maximum of 36.3 ± 2.7 mm Hg but had no effect on serum gastrin. Antral distention with water or 0.1 M $NaHCO_3$, as well as antral perfusion with 0.1 M HCl followed by 0.1 M $NaHCO_3$, perfusion with 0.1 M $NaHCO_3$ followed by 0.1 M HCl, or peptone failed to affect LESP. It is concluded that the antrum and endogenous gastrin have little if any effect on LESP in dogs.

4310 EFFECT OF HISTAMINE AND HISTAMINE ANTAGONISTS ON HUMAN LOWER ESOPHAGEAL SPHINCTER FUNCTION.

(Eng.) Kravitz, J. J.; Snape, W. J., Jr.; Cohen, S. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 74(2):435-440; 1978.

The effect of histamine phosphate and specific histamine antagonists on human lower esophageal sphincter (LES) pressure was investigated in 31 fasting, healthy subjects. Continuous i.v. infusions of histamine (2.0-40.0 µg/kg/hr) gave graded increases in LES pressure with a peak response of 37.8 ± 4.6 mm Hg at 20.0 µg/kg/hr. The LES response was not altered by diphenhydramine (50 mg, i.v.), but was completely blocked by cimetidine infusion (4.0 mg/kg/hr). Also, p.o. cimetidine (300 mg) antagonized any increase in LES pressure during histamine infusion at a dose shown to give the maximal LES response. Despite this effect of cimetidine in antagonizing the maximal LES response to histamine, p.o. cimetidine at 200, 300, and 400 mg failed to alter basal LES pressure over a 3-hr period. Cimetidine also failed to alter the LES response to i.v. pentagastrin or p.o. beef hydrolysate. These studies suggest that (1) human LES pressure increases in response to i.v. histamine phosphate through its action at an H_2-receptor, (2) the H_1-receptor has no apparent role in the human LES response to histamine, and (3) H_2-antagonism with cimetidine has no effect on the human LES basal pressure or its response to gastrin stimulation.

4311 THE MYOELECTRIC COMPLEX OF THE SMALL INTESTINE AND VARIATIONS OF ALIMENTARY FLOW IN SHEEP.

(Fre.) Bueno, L. (Ecole Nationale Veterinaire, 31076 Toulouse Cedex, France). *C. R. Soc. Biol. (Paris)* 171(4):959-964; 1977.

The variations in the intestinal flow rate of sheep were compared to changes in the electrical activity of intestinal smooth muscle recorded by six groups of electrodes spaced from the antrum to the ileocecal junction while the animals were restrained in metabolic cages. In sheep fed a control diet, myoelectric complexes originated in the duodenal bulb at 70- to 100-min intervals and were propagated along the small intestine at a mean velocity of 21 cm/min. These complexes consisted of irregular activity lasting approximately 56 min followed by 5 min of regular and maximal activity and a resting stage. When the sheep were fasted for 48 hr, the chyme volume dropped from 400 ml/hr to 200 ml/hr, the duration of the irregular phase was reduced to 37 min, the duration of the regular phase increased to 7.5 min, and the velocity of propagation rose to 35 cm/min. In overfed sheep, the chyme volume rose to 520 ml/hr; the irregular phase lasted 84 min, but the regular phase or velocity did not differ significantly from controls. It is concluded that changes in intestinal flow rate are affected by the duration, number, and velocity of propagation of the myoelectric complexes, which propel ingesta through the small intestine.

4312 MOTILITY AND GLUCOSE ABSORPTION IN THE SMALL INTESTINE OF SHEEP.

(Fre.) Fioramonti, J.; Ruckebusch, M. (Ecole Nationale Veterinaire, 31076 Toulouse Cedex, France). *C. R. Soc. Biol. (Paris)* 171(4):964-969; 1977.

To examine the relationship between intestinal motility and/or transit and absorption, recurring myoelectric complexes and glucose absorption in the small intestine of three sheep were studied *in vivo* in isolated 2-m jejunal loops, using electrodes and a perfusion marker technique. Glucose was perfused through the jejunal segment at 37.5 mg/min, giving an intestinal flow of 225 ml/hr when the transit of ingesta was interrupted, or 480 ml/hr when the ingesta were allowed to pass normally through the loop. When the intestinal transit was not interrupted, the net absorption of glucose was 30% during the regular activity phase (RAP) and resting phase (RP) of the myoelectric complexes, and it decreased to 10% during the irregular activity phase (IAP), reaching its lowest point 2-6 min before the occurrence of the RAP. When glucose alone flowed through the loop, absorption was maximal during the RP, decreased during the IAP, and became minimal during the RAP. The intestinal flow rate, which was nil during the RP, increased to 8.3 ml/min during the RAP and to 32.4 ml/min during the IAP. These results suggest that, under normal physiological conditions, intestinal absorption occurs mainly during the RAP of myoelectric complexes.

4313 EFFECTS OF ENDOGENOUS PROSTAGLANDIN E ON INTESTINAL MOTILITY.

(Eng.) Sanders,

K. M.; Ross, G. (Mayo Foundation, Rochester, MN 55901). *Am. J. Physiol.* 234(2):E204-E208; 1978.

The role of endogenous prostaglandin E (PGE) in the regulation of intestinal motility *in situ* was studied in anesthetized cats. The basal concentration of ileal PGE was found by radioimmunoassay to be 3.3 ± 0.6 ng/wet weight (n=12). Intramesenteric arterial infusion of acetylcholine (ACh, 100 μg/min) increased intestinal motility, and PGE concentration rose to 6.7 ± 0.8 ng/g. The i.v. infusion of indomethacin (4 mg/kg) enhanced spontaneous and ACh-induced motility and abolished the ACh-induced rise in ileal PGE concentration. It is concluded that basal PGE synthesis limits the motility of the resting and ACh-stimulated cat ileum.

4314 FACTORS AFFECTING DELIVERY OF BILE TO THE DUODENUM IN MAN. (Eng.) Ashkin, J. R.; Lyon, D. T.; Shull, S. D.; Wagner, C. I.; Soloway, R. D. (Hosp. Univ. Pennsylvania, 3600 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 74(3): 560-565; 1978.

Studies utilizing balloon occludable T or duodenal tubes in subjects with and without gallbladders were undertaken to identify the contribution of the gallbladder, the sphincter of Oddi, and bile salts to the delivery of bile to the duodenum. Patients with and without a functional sphincter of Oddi and with and without a gallbladder were compared. The presence of a functional sphincter of Oddi in duodenal-tube patients reduced bile salt output by more than 67% from that observed in T-tube patients. When cholecystectomized and normal patients were compared using the duodenal tube, peak bile salt output was significantly increased in normal subjects ($p<0.02$), reflecting gallbladder contraction, but total bile salt output was not significantly increased, suggesting that the gallbladder has a minor role in bile delivery. Exogenous cholecystokinin infusion (0.0625 Crick-Harper-Raper U/kg/min, i.v.) produced much more stable bile secretion than did endogenous release of cholecystokinin by intraduodenal infusion of essential amino acids. This rhythmic release of bile after endogenous cholecystokinin release was related to the concentration of bile salts in the intestinal lumen. Thus, delivery of bile to the duodenum is wave-like and is predominantly controlled by the sphincter of Oddi.

4315 THE EFFECT OF MOTILIN ON THE ELECTRICAL ACTIVITY OF RABBIT CIRCULAR DUODENAL MUSCLE. (Eng.) Riemer, J.; Kolling, K.; Mayer, C. J. (Institut fur Physiologie, Universitat Munchen, Pettenkoferstrasse 8, D-8000 Munchen, W. Germany). *Pfluegers Arch.* 372(2):243-250; 1977.

The effect of 13-norleucine motilin on electrical activity and membrane resistance of the rabbit circular duodenal muscle was studied with intracellular recording techniques. Electrical slow waves without spikes occurred in Krebs solution made twice hypertonic by the addition of sucrose. The slow waves were of the basic organ-specific rhythm (BOR) type. Their mean frequency was 18.1/min, their mean amplitude from trough to peak was 11.4 mV, and their mean membrane potential during the trough was -59.1 mV. Motilin (1×10^{-7} g/ml) caused membrane depolarization by a mean of 10.9 mV. Membrane resistance was reduced. The BOR slow waves were either reduced or abolished by motilin. Slow fluctuations of membrane potential characteristic of a minute-type rhythm (MR) appeared after the addition of the hormone, and trains of spikes occurred at the crests of the MR and were associated with contraction of the muscle. Two mechanisms may account for the correlation between membrane resistance and voltage: (1) motilin may increase conductance for one or more ion species whose equilibration potentials have lower negative values than the resting membrane potential or (2) motilin may induce some unknown mechanism that shifts the potential to lower negative values, constituting a decrease of membrane resistance as a consequence of rectifying properties.

4316 ON THE INFLUENCE OF LOW EXTRACELLULAR CALCIUM LEVEL ON THE CONTRACTILITY AND ULTRASTRUCTURE OF SMOOTH MUSCLE CELLS OF ILEUM AND COLON. (Eng.) Lowe, H.; Bergmann, J. (Akademie der Wissenschaften der DDR, Institut fur Wirkstofforschung, Alfred-Kowalke-Strasse 4, DDR-1136, Berlin, E. Germany). *Exp. Pathol. (Jena)* 14(3/4):180-188; 1977.

The effect of a low extracellular calcium concentration on the contractility and ultrastructure of the smooth muscle cells of the isolated guinea pig ileum and colon was studied. After the calcium level in the organ bath was decreased to one-tenth of the normal concentration, acetylcholine-induced ileal contraction decreased by 50%. The same effect was seen after the addition of 5×10^{-7} M verapamil to normal bath fluid (Tyrode solution). When isolated strips of ileum were incubated in a calcium-free bath for 20 min (37 C), myosin-like filaments were observed in the smooth muscle cells of the tunica muscularis. The same ultrastructural changes were demonstrated when verapamil (2×10^{-5} M) was added to the medium. In contrast, the taenia coli showed no changes in contractility when the calcium level in the organ bath was lowered, and there was no formation of myosin-like filaments. After the addition of verapamil, the contractility of the taenia coli decreased, but not in the same degree as that in the ileum. Ultrastructural changes were not demonstrated in the sarcoplasm of the smooth muscle cells with verapamil. The authors conclude that the contraction of the smooth muscle cells in the ileum is mainly caused by the influx of calcium from the extracellular space. In the taenia coli, however, contraction must be caused by the efflux of calcium from storage sites in the sarcoplasm. The formation of thick myofilaments may be a result of a change in myosin structure following a change in calcium concentration.

4317 ENDOGENOUS PROSTAGLANDIN E AND CONTRACTILE ACTIVITY OF ISOLATED ILEAL SMOOTH MUSCLE. (Eng.) Sanders, K. M. (Mayo Foundation, Rochester, MN 55901). *Am. J. Physiol.* 234(2):E209-E212; 1978.

The effects of endogenous prostaglandin E (PGE) on the contractile activity of isolated cat ileal muscle rings were studied. Force development in circularly oriented muscle fibers was recorded. The muscles contained a mean basal PGE concentration of 1 ± 0.6 ng/g wet weight, as measured by radioimmunoassay. Acetylcholine (ACh) administration or elevated potassium level caused contractions and enhanced PGE concentration ($p<0.05$). The removal of Ca^{2+} from solutions high in potassium blocked contraction, but PGE concentration still increased ($p<0.02$). The prostaglandin synthetase inhibitors, indomethacin and 5,8,11,14-eicosatetranoic acid reduced PGE concentration in muscles (<50 pg PGE/g muscle) and increased the magnitude of contractions induced by either ACh or elevated potassium. Spontaneous contractions were observed in many tissues after inhibition of PGE synthesis. Endogenous PGE limits spontaneous and depolarization-induced muscular activity in cat ileal circular muscle. PGE synthesis was increased by depolarizing stimuli, whether or not contractions were blocked by the removal of external calcium.

4318 QUALITATIVE AND QUANTITATIVE EVALUATION OF INTERNAL ANAL SPHINCTER FUNCTION IN THE NEWBORN. (Eng.) Boston, V. E.; Cywes, S.; Davies, M. R. Q. (Red Cross War Memorial Children's Hosp., Univ. Cape Town, South Africa). *Gut* 18(12): 1036-1044; 1977.

One hundred one normal neonates were examined manometrically in the first day of life to assess anorectal function. To overcome some of the difficulties in subjective interpretation of results, the stimuli used and the response pattern seen in the anal canal were measured. In the unstimulated state, all subjects demonstrated rhythmical changes in anal canal tone. Mean maximal intraluminal pressure in the anal canal decreased significantly after 10 hr of age ($p<0.01$) and after the first meconium stool ($p<0.02$). Only 5 of the 101 examined on the first day of life had an abnormal manometric response. It is significant ($p=0.0194$) that none of these had passed meconium at the time of examination, and that all had a normal response pattern at the age of 28 hr. In 20 babies, the sensitivity of the anorectal reflex was measured and found to be significantly increased ($p<0.01$) on the third day of life compared with the first. The quantitative changes in anorectal reflex function in the newborn are thought to be related to the state of physiological "constipation," which exists *in utero* and in the early neonatal period. The results indicate that a normal response pattern can be obtained in healthy babies after the first day of life. Consequently, anorectal manometry will be meaningful as a diagnostic method thereafter in the neonatal period. It is suggested that measurement of the stimulus and the response will add useful information and reduce subjective error in interpretation of results.

4319 SOMATOSTATIN INHIBITS GASTRIC MOTILITY IN RESPONSE TO DISTENTION. (Eng.) Stadaas, J. O.; Schrumpf, E.; Hanssen, K. F. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 13(2): 145-148; 1978.

The effect of somatostatin on gastric motility was studied in six healthy volunteers before and after stepwise gastric distention. Distention was performed by filling a flaccid thin-walled bag, which was connected with a low pressure transducer for measuring intragastric pressure variations. Stepwise increase in gastric volume from 0-600 ml caused graded increases in gastric motility. No significant change was seen in the plasma gastrin level. When gastric distention was performed concomitantly with constant infusion of somatostatin (0.05 mg/hr or 0.50 mg/hr) in the same individuals on different days, motility was significantly reduced ($p<0.05$) with both doses of somatostatin, without any changes in the plasma gastrin concentration. It is concluded that somatostatin may have a physiological effect in the regulation of gastric motility. This effect of somatostatin on motility seems to be independent of any effect on the gastrin concentration.

SECRETION AND METABOLISM

Stomach

4350 PLASMA GASTRIN AND GASTRIC SECRETORY RESPONSE TO DUODENAL PERFUSION WITH LIVER EXTRACT IN HEALTHY HUMAN SUBJECTS. (Eng.) Grabner, P.; Semb, L. S.; Schrumpf, E.; Myren, J. (Diakonhjemmets Hosp., Oslo 3, Norway). *Scand. J. Gastroenterol.* 12(7):865-868; 1977.

The responses of plasma gastrin and gastric secretion were determined in eight healthy subjects during duodenal perfusion with liver extract (LE). After a 1-hr period without perfusion, the duodenum was perfused for 2 hr with 15% LE (pH 4.5-5.5, 1,027 mOsm/kg water) at a rate of 100 ml/hr, either alone or in combination with i.v. infusion of different doses of exogenous pentagastrin (0.1 μg/kg during the first hour, 3 μg/kg during the second hour). Reflux to the stomach was monitored by addition of radioactive B_{12} to the perfusates. During perfusion of the proximal duodenum in six subjects, in whom reflux of the perfusates was less than 4%, only a slight and inconstant change in plasma gastrin was seen. Gastric acid and pepsin outputs were increased to about 18% and 25% of the maximal pentagastrin stimulation, resp. Although 15% LE was shown to release gastrin by antral perfusion, such release was not found by duodenal perfusion, except where reflux to the antrum was seen. The results suggest that intestinal stimulation of gastric secretion exists, but that it is not gastrin dependent.

4351 HEPATIC INACTIVATION OF GASTRINS OF VARIOUS CHAIN LENGTHS IN DOGS. (Eng.)

Strunz, U. T.; Thompson, M. R.; Elashoff, J.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 74(3):550-553; 1978.

Acid secretion in response to portal or systemic venous infusion of a series of progressively longer fragments of the carboxyl terminal portion of human gastrin was studied in dogs with gastric fistulae and with transposition of the portal vein and the inferior vena cava. Pentagastrin G6, G7, G8, G9, G10, G13, G17, and G34 were studied. Potency by portal venous infusion relative to systemic venous infusion was used as an index of hepatic inactivation. Fragments with eight or fewer amino acid residues were more than 90% inactivated by hepatic transit. Fragments with nine or more amino acid residues were more resistant to hepatic inactivation than were shorter fragments. For fragments with 7 to 17 amino acid residues, increasing the chain length was accompanied by progressive increase both in hepatic resistance to inactivation and in potency for stimulation of acid secretion, suggesting that resistance to hepatic inactivation may be a major determinant of potency.

4352 THE ROLE OF ADRENALINE AND OF THE VAGUS IN GASTRIN RELEASE AND ACID SECRETION IN DOGS. (Eng.)

Brandsborg, O.; Ornshot, J.; Brandsborg, M.; Christensen, N. J. (Kommunehospitalet, DK-8000 Aarhus C, Denmark). *Eur. J. Clin. Invest.* 7(6):481-486; 1977.

To study the role of epinephrine and of the vagus in gastrin release and acid secretion, serum gastrin levels, gastric acid secretion, and plasma epinephrine levels were measured in response to the i.v. injection of 2-deoxy-D-glucose (100 mg/kg) or insulin (0.25 IU/kg) in six dogs with gastric fistulae before and after denervation of the antrum and the intestine (antral-intestinal vagotomy). The same six dogs were also studied pre- and postoperatively in the basal state and after a 200-g beef meal of standard dog food. Serum gastrin levels and gastric acid secretion were also measured in four of the same dogs during the i.v. infusion of epinephrine (2, 4, 6, or 8 μg/min) in doses that produced an elevation of plasma epinephrine to levels occurring during hypoglycemia or after the injection of 2-deoxy-D-glucose. Antral-intestinal vagotomy reduced the basal gastrin concentration slightly and basal gastric acid secretion considerably ($p<0.05$); the rise in serum gastrin in response to 2-deoxy-D-glucose and hypoglycemia was abolished, while the increase in gastric acid secretion was reduced. Beef meal-stimulated gastrin secretion was the same before and after vagotomy. The i.v. infusion of epinephrine had no effect on either serum gastrin concentration or gastric acid secretion. It is concluded that, in the dog, in contrast to man, gastrin release after insulin is dependent on an intact vagus. Gastrin release by epinephrine in the dog does not appear to be physiological since it is not achieved by the amount of epinephrine released in response to hypoglycemia.

4353 ROLE OF GASTRIN HEPTADECAPEPTIDE IN THE ACID SECRETORY RESPONSE TO AMINO ACIDS IN MAN. (Eng.)

Feldman, M.; Walsh, J. H.; Wong, H. C.; Richardson, C. T. (Veterans Admin. Hosp., Dallas, TX 75216). *J. Clin. Invest.* 61(2):308-313; 1978.

The relation between gastrin release and acid secretory response was studied in eight healthy subjects. An isotonic mixed amino acid solution (casein hydrolysate) was continuously infused into the stomach of each subject. Acid secretion, measured by *in vivo* intragastric titration, increased 12.8 mEq/hr over the response to intragastric infusion of isotonic saline. Plasma gastrin heptadecapeptide (G-17) concentration, measured by specific radioimmunoassay, increased 13 pM during intragastric amino acid infusion. To determine whether this rise in plasma G-17 concentration could account for some or all of the acid secretory response, several doses of synthetic human G-17-I (4.0, 10.0, 25.0, and 62.5 pmol/kg/hr) were infused i.v. into the same subjects. During this infusion, the stomach was continuously infused with isotonic saline. By graphically relating plasma G-17 concentration during i.v. G-17 infusion to concomitant acid secretion, it was determined that a 13-pM rise in plasma G-17 concentration could increase acid secretion 14.8 mEq/hr. Therefore, the rise in plasma G-17 concentration during intragastric amino acid infusion could have produced all of the observed acid secretory response. This suggests that gastrin heptadecapeptide is the major physiologic mediator of the human acid secretory response to meals containing mixed amino acids.

4354 MACROMOLECULAR SECRETION BY ISOLATED GASTRIC MUCOSA: FUNDAMENTAL DIFFERENCES IN PEPSINOGEN AND INTRINSIC FACTOR SECRETION. (Eng.)

Kapadia, C. R.; Donaldson, R. M., Jr. (Veterans Admin. Hosp., West Haven, CT 06516). *Gastroenterology* 74(3):535-539; 1978.

The secretion of pepsinogen and intrinsic factor (IF) in response to various known stimulators and inhibitors of gastric acid secretion was examined in isolated rabbit gastric mucosa maintained in organ culture. Acetylcholine (10^{-8} M) stimulated both pepsinogen ($p<0.01$) and IF ($p<0.01$) secretion, and this stimulation was blocked by atropine (10^{-2} M). Parasympatholytic agents did not alter unstimulated (basal) secretion of pepsinogen even at high concentrations (atropine, 10^{-2} M or propantheline bromide, 5×10^{-3} M); however, at these concentrations basal IF secretion was abolished. Histamine (10^{-4} and 10^{-2} M) had no effect on pepsinogen secretion but stimulated IF secretion ($p<0.001$). Cimetidine (2×10^{-3} M) reduced both basal and histamine-stimulated IF secretion (by 42%

and 100%, resp.), but pepsinogen secretion remained unaltered. The gastric mucosal surface was not exposed to HCl but was constantly buffered by culture medium at pH 7.4. When 50 mN HCl was applied to the mucosal surface of the biopsies, pepsinogen secretion doubled ($p<0.001$), but IF secretion was abolished. These studies document that fundamental differences exist in the responses of pepsin- and IF-secreting cells and that H^+ ions bathing the mucosal surface of the stomach may influence the results of experiments designed to examine the mechanisms of gastric mucosal macromolecular secretion.

4355 PROTEIN SYNTHESIS INHIBITORS AND GASTRIC ACID SECRETION.

(Eng.) Carlisle, K. S.; Reagan, C. R.; Hersey, S. J. (Emory Univ., Atlanta, GA 30322). *Gastroenterology* 74(3):504-510; 1978.

The involvement of *de novo* protein synthesis in acid secretion by the *in vitro* bullfrog gastric mucosa was examined using the inhibitors cycloheximide (5 µg/ml) and puromycin (80 µg/ml). Both inhibitors reduced ^3H-leucine incorporation by more than 90%. The inhibition of protein synthesis had no influence on spontaneous acid secretion, nor did it affect secretory stimulation by histamine, carbachol, pentagastrin, or theophylline. Oxygen consumption by nonstimulated and theophylline-stimulated tissues was shown to be independent of protein synthesis. The dramatic morphological changes observed in oxyntic cells during a transition from rest to active secretion persisted in cycloheximide- and puromycin-treated tissues. Stereological analysis of the apical membrane surface area density failed to demonstrate any quantitative influence of protein synthesis inhibition. These studies quantitatively confirm that protein synthesis is not required for the biochemical and morphological events involved in acid secretion by the *in vitro* frog gastric mucosa.

4356 THE ACTIONS OF SECRETAGOGUES ON OXYGEN UPTAKE BY ISOLATED MAMMALIAN PARIETAL CELLS.

(Eng.) Soll, A. H. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *J. Clin. Invest.* 61(2):370-380; 1978.

The action of histamine, carbamylcholine, and gastrin on oxygen uptake by canine fundic mucosal cells was studied *in vitro*. Viable mucosal cells were prepared by exposure of separated mucosa sequentially to collagenase and EDTA. Oxygen consumption, determined by polarography, was chosen as an index of physiological response of mucosal cells to secretagogues. Isobutyl methyl xanthine (IMX), carbamylcholine, histamine, and gastrin each independently stimulated oxygen uptake by the unfractionated mucosal cells. The response to histamine was greatly enhanced when 0.1 mM IMX was present. In fractions of varying parietal cell content obtained with the Beckman elutriator rotor, basal and stimulated oxygen uptake correlated with the parietal cell content of the fractions. The percentage increases in oxygen uptake in response to histamine, gastrin, carbamylcholine, and IMX were similar in enriched fractions with from 50% to 85% parietal cells and in unenriched starting fractions. The normalized dose-response relations for histamine with an IMX background and for carbamylcholine were also similar in these two fractions. The specificity of these responses was tested using metiamide and atropine. Neither metiamide (0.1 mM) nor atropine (10 µM) inhibited basal oxygen uptake. Histamine, studied with an IMX background, was inhibited by metiamide but not by atropine, while carbamylcholine was inhibited by atropine but not by metiamide. Neither metiamide nor atropine inhibited gastrin-stimulated oxygen uptake. These data indicate that in this *in vitro* system, parietal cells account for most of the increase in oxygen uptake produced by exposure to gastric secretagogues and that histamine, gastrin, and carbamylcholine each independently stimulate oxygen uptake by the parietal cell. The specificity displayed by atropine and metiamide in this system suggests that the parietal cell has specific receptors for each of these secretagogues.

4357 THE INTERACTION OF HISTAMINE WITH GASTRIN AND CARBAMYLCHOLINE ON OXYGEN UPTAKE BY ISOLATED MAMMALIAN PARIETAL CELLS.

(Eng.) Soll, A. H. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *J. Clin. Invest.* 61(2):381-389; 1978.

The interactions between histamine and gastrin and between histamine and carbamylcholine and the effects of atropine and metiamide on these interactions were studied, using oxygen uptake as an index of the physiological response of isolated parietal cells. Parietal cells were isolated from canine fundic mucosa by sequential exposure of separated mucosa to collagenase and EDTA. Potentiating interactions between histamine and carbamylcholine and between histamine and gastrin were demonstrated. Against a histamine (0.1 and 1 µM) plus isobutyl methyl xanthine (0.1 mM) background, the dose for 50% response for gastrin was approximately 1 nM, and the maximal response was obtained at 0.1 µM. When added to these combinations of stimulants, metiamide and atropine retained their respective specificities against stimulation by histamine and carbamylcholine, in that responses were inhibited to the level that was seen when the component of the pair that was not inhibited was given alone. The observation that histamine plus gastrin and histamine plus carbamylcholine produce maximal responses that are greater than the maximal response to histamine alone supports the hypothesis that these agents each have direct actions on parietal cells. These observations are not consistent with the hypothesis that histamine is the sole mediator for the effects of other secretagogues. Furthermore, the inhibitory effects of atropine and metiamide on the specific cholinergic and histaminic components of the interactions that occur between secretagogues provide a possible explanation for the apparent lack of specificity of these agents on *in vivo* acid secretion.

4358 HISTAMINE AUGMENTS GASTRIC ULCERATION PRODUCED BY INTRAVENOUS ASPIRIN IN CATS.

(Eng.) Hansen, D. G.; Aures, D.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 74(3):540-543; 1978.

Studies were carried out in conscious cats to determine whether the addition of histamine to the i.v. infusion of aspirin would produce more severe ulcers and cause them to appear earlier. A continuous infusion of aspirin (0.063-4.0 mg/kg/hr) for 36 hr did not produce gastric ulcers when given alone but did when combined with histamine-2HCl (160 μg/kg/hr, i.v.). The ulcers were mainly antral in location. The incidence and severity of ulcers increased with duration of the infusion up to 36 hr and with dose of aspirin up to 4 mg/kg/hr. With the highest doses and longest durations, some of the antral ulcers perforated. Antral ulcers occurred in more than half of the cats receiving 0.25 mg/kg/hr or more of aspirin for 36 hr or receiving 4 mg/kg/hr of aspirin for ≥6 hr. Intravenous aspirin plus the intragastric infusion of 150 mM HCl (40 ml/hr) for 16 hr also produced gastric ulcers. Plasma salicylate concentrations were less than 350 μg/ml with all doses and durations of aspirin used (400 μg/ml is regarded as the upper limit of the therapeutic range in man). These studies show that when the stomach is acidified by giving histamine i.v. or HCl intragastrically, i.v. aspirin produces large deep gastric ulcers.

4359 EFFECT OF MAST CELL DEGRANULATION ON GASTRIC MUCOSAL DAMAGE PRODUCED BY SODIUM TAUROCHOLATE IN THE RAT.

(Eng.) Rees, W. D. W.; Rhodes, J.; Williams, B. C.; Owen, E.; Newcombe, R. G. (Mayo Clinic, Rochester, MN). *Gastroenterology* 74(3):492-495; 1978.

The source of the histamine released during damage to the gastric mucosa was investigated in rats using perfused total gastric pouches. Two groups of rats were treated with either i.p. normal saline or compound 48/80, an agent that produces mast cell degranulation, over a 5-day period (100 μg on the first day, increasing by daily increments of 100 μg to 500 μg on the fifth day). On the fifth day, total gastric pouches were prepared and connected to a perfusion circuit that enabled a 20-ml volume to be circulated through the pouches. The experiments consisted of three 30-min periods during which transmucosal potential difference was monitored and ionic (hydrogen and sodium) flux was measured; standard acid solution was used in the first two periods and a taurocholate solution in the third. Sodium taurocholate produced a significant increase in ionic flux and fall in the potential difference ($p<0.001$), the magnitude of the changes being similar in the 48/80- and saline-treated groups. Histamine was released from the mucosa in significantly greater amounts ($p<0.001$) during the taurocholate period, and the increase was similar in both groups of rats. Histological examination of the stomachs confirmed mast cell degranulation in the 48/80-treated groups. It is concluded that the histamine released during mucosal damage is probably derived from the "nonmast cell pool" and that this histamine may play a role in mediating the mucosal damage.

4360 EFFECTS OF STRESS AND HIGHLY SELECTIVE VAGOTOMY ON MAST CELLS IN THE WALL OF THE RAT STOMACH.

(Fre.) Forgacs, A.; Patricio, J.; Duchatelle, J. P.; Germain, M. (Centre d'experimentation animale, Universite Paris XII, 6, rue du General-Sarrail, 94000 Creteil, France). *J. Chir. (Paris)* 114(3):225-231; 1977.

The effects of immobilization stress and highly selective vagotomy (HSV) on the number and appearance of mast cells of the gastric wall, visualized by Alcian Blue-Safranin staining, were studied in 70 adult male Wistar rats. Group 1 (10 rats) served as control. Group 2 (15 rats) was subjected to 24-hr stress. Group 3 (30 rats) underwent HSV and group 4 (15 rats) was stressed 40 days after HSV. HSV alone caused a significant increase in the mast cell count ($p=0.001$) during the 6-month observation period. Stress caused ulcers in 94.6% of all rats that did not undergo HSV; the overall mast cell count showed no significant change compared with the controls, but the red-staining mast cells disappeared. Stress after HSV caused ulcer in 26.7% of the rats; the total number of mast cells diminished compared with the nonstressed, vagotomized rats (17.9 cells/mm^2 versus 238 cells/mm^2), but the percentage of blue-staining mast cells increased from 41.2% to 86.6%, and the percentage of the red-staining mast cells dropped from 44.4% to 3.9%. The findings indicate that the vagus nerve influences the mast cell count in the gastric wall and regulates the ratio of red-staining to blue-staining mast cells. Stress leads to the disappearance of red-staining mast cells, which may be independent of the vagal innervation. The long-term consequences of HSV should be further studied.

SECRETION AND METABOLISM

Pancreas

4401 STUDIES ON THE SECRETORY PROCESS IN EXOCRINE PANCREAS CELLS II. C57 BLACK AND BEIGE MICE. (Eng.) Novikoff, A. B.; Quintana, N.; Mori, M. (Albert Einstein Coll. Medicine, Yeshiva Univ., Bronx, NY). *J. Histochem. Cytochem.* 26(2): 83-93; 1978.

Electron microscopic and cytochemical studies were performed on the pancreas of the C57 black mouse and its beige mutant (an animal homologue of the Chediak-Higashi syndrome) to determine whether the packaging of secretory materials occurs in GERL, an area of endoplasmic reticulum (ER) that displays acid phosphatase (AcPase) but not thiamine pyrophosphatase (TPPase) activity and from which lysosomes appear to form. In the black mouse, electron microscopy revealed that the GERL includes condensing vacuoles, coated vesicles, and rigid lamellae. The rough ER extends to GERL through gaps between Golgi stacks. Electron-opaque materials were not encountered, either in GERL or in other areas of ER. In the beige mouse, electron microscopy demonstrated that most of the GERL appears to consist of wide dilated portions filled with electron-opaque materials that seem to be packaged into huge residual body-type lysosomes. This GERL also showed AcPase-positive condensing vacuoles, rigid lamellae, and coated vesicles. In the beige mouse, therefore, processing and packaging of secretory materials apparently continue normally despite the formation of abnormal granules of GERL. The studies reported here establish that GERL can be specialized into different regions in the pancreatic acinar cell and extend the concept of the complexity of transport within the ER.

4402 CHANGES IN PANCREATIC AND INTESTINAL ENZYME ACTIVITIES FOLLOWING CHENODEOXYCHOLIC ACID FEEDING. (Eng.) O'Donnell, M. D.; Fitzgerald, O.; McGeeney, K. F. (Dept. Medicine and Therapeutics, Univ. Coll., "Woodview," Stillogran Rd., Dublin 4, Ireland). *Scand. J. Gastroenterol.* 12(6): 683-687; 1977.

The effect of p.o. chenodeoxycholic acid (CDCA) on pancreatic and intestinal enzyme levels was examined by feeding 0.5% CDCA in a normal diet to male mice (inbred bca strain). Groups of eight mice each were killed on days 3, 23, and 70 after the start of CDCA feeding. Pancreatic lipase concentration and specific activity were significantly increased after 3 days and 70 days ($p<0.0005$ and $p<0.01$) on the CDCA-containing diet but not at 23 days. Amylase and trypsin activities per gram of pancreas were significantly higher at 23 days ($p<0.05$ for both) and 70 days ($p<0.01$ and $p<0.05$, resp.) on the diet compared to controls. Expressed as specific activities (U/mg protein) the difference between the experimental and control groups is significant only at 70 days ($p<0.025$) with respect to amylase and is not significant with respect to trypsin. Pancreatic protein concentration was significantly increased at 3 and at 70 days ($p<0.005$ and $p<0.01$, resp.) but not at 23 days compared to controls; the intestinal protein concentration was significantly higher only after 70 days ($p<0.05$). Intestinal amylase levels did not change during the experiments. Intestinal α-glucosidase activity was significantly increased after 3 days, expressed either as concentration ($p<0.0005$) or as specific activity ($p<0.0025$). However, at 70 days on the CDCA-containing diet, the difference was significant ($p<0.02$) only when expressed as a concentration; the difference was never significant when expressed as a specific activity. The increase in the digestive enzyme concentration of the pancreas caused by CDCA feeding is somewhat similar to the effect of feeding soybean trypsin inhibitors. The higher enzyme levels may result from increased synthesis, probably leading to increased secretion of enzymes.

4403 THE ACTION OF BOMBESIN AND LITORIN ON PANCREATIC SECRETION OF THE RAT. (Eng.) Linari, G.; Linari, M. B.; Lutoslawska, G. (Istituto di Farmacologia Medica I, Piazzale delle Scienze 5, 00185 Roma, Italy). *Rend. Gastroenterol.* 9(3):179-184; 1977.

The effects of bombesin (BBS) and litorin (LIT) on pancreatic secretion were investigated in anesthesized female Wistar rats and compared with the effect of cerulein (C). Both BBS and LIT strongly stimulated pancreatic flow and amylase output in a dose-dependent manner, with a short latency in the onset of the response. With regard to amylase secretion the threshold dose was 5-10 ng/kg/min for BBS and 15-20 ng/kg/min for LIT. The maximum response of both BBS and LIT was observed at an infusion rate of 303.75 ng/kg/min. Similar responses were obtained with C infused at rates 10 times lower on a weight basis. The calculated maximal responses of amylase output to bombesin and litorin were similar but, on the basis of ED_{50}, bombesin was 36% more potent than LIT. There was a statistically significant correlation (r=0.96) between pancreatic flow and amylase secretion, indicating that no change in amylase concentration occurred during stimulation with either polypeptide. Pancreatic secretion elicited by BBS, LIT, or C was practically unaffected either by atropine administration or by enterectomy. The latter finding makes it unlikely that BBS and LIT act on the rat pancreas through cholecystokinin (CCK) release, unless CCK is released by sites other than the intestine. It is suggested that the effect of BBS and LIT on the rat pancreas is due primarily to direct stimulation of the acinar cell.

4404 THE ACTION OF CAERULEIN ON THE PANCREATIC SECRETION OF THE RAT. (Eng.) Linari, G.; Linari, M. B. (Inst. Medical Pharmacol. I, Univ. Rome, 00185 Rome, Italy). *Farmaco* [*Prat.*] 32(12): 611-616; 1977.

The response of the pancreas to i.v. cerulein was studied in female Wistar rats. Cerulein stimulated both juice flow and amylase output. A good dose-response relationship was obtained for infusion rates of the peptide ranging from 1.25 to 33.75 ng/kg/min. At the rate of 101.25 ng/kg/min, the pancreatic response decreased. The rate of amylase output rapidly increased to 3.75 ng/kg/min, remaining constant thereafter. Atropine (5 mg/kg, 10 min before cerulein; or 30 µg/kg/min, starting 30 min after cerulein infusion) did not appreciably affect the pancreatic response. This study confirms that cerulein is a potent stimulant of pancreatic secretion in the rat.

4405 PANCREATIC ACINAR CELL CHANGES INDUCED BY CAERULEIN, VINBLASTINE, DEUTERIUM OXIDE, AND CYTOCHALASIN B IN VITRO. (Eng.) Stock, C.; Launay, J. F.; Grenier, J. F.; Bauduin, H. (Unite de Recherches 61 de l'INSERM, Avenue Moliere, 67200 Strasbourg, France). *Lab. Invest.* 38(2):157-164; 1978.

To elucidate the possible role of microfilaments and microtubules in secretory processes, the effects of cerulein, vinblastine (VB), deuterium oxide (D_2O), and cytochalasin B upon both the structure and the function of the pancreatic acinar cell were studied *in vitro* using rat pancreatic fragments. Cerulein (10 ng/ml) stimulated the release of enzymes and induced the appearance of numerous exocytotic images at the apical part of the acinar cell. Whereas VB (5×10^{-5} M) and D_2O (55%) inhibited the secretory response to cerulein, they did not affect the general ultrastructure of the acinar cell. Prolonged incubation in the presence of VB provoked the disappearance of microtubules and the massive precipitation of microcrystalline material in all parts of the cytoplasmic space. Numerous microtubules were found in the acinar cell after exposure to D_2O. Although VB and D_2O did not alter the microfilamentous network localized at the apical part of the cell, cytochalasin B (2×10^{-5} M) disrupted it. This drug decreased the number of microvilli projecting into the enlarged acinar lumen. Whether cytochalasin B was used alone or in association with VB or D_2O, it inhibited the secretory response to cerulein and prevented exocytosis. It is suggested that microfilaments act in a later step of the secretory cycle, i.e., exocytosis, than do microtubules.

4406 ENZYME SPECTRUM OF THE EXOCRINE PANCREAS OF VARIOUS SPECIES AND ITS SIGNIFICANCE IN ENZYME SUBSTITUTION THERAPY. (Ger.) Berndt, W.; Maas, R.; Strassner, A. (I. Medizinische Universitatsklinik, Martinistrasse 52, 2000 Hamburg 20, W. Germany). *Therapiewoche* 27(35):6090, 6092, 6095-6098, 6101-6104, 6107; 1977.

The enzyme pattern of the exocrine pancreas of the hog, cattle, sheep, horse, and pike, and the suitability of these enzymes in human enzyme substitution therapy were studied. Considerable species-specific differences were found in the lipase, amylase, trypsin, and chymotrypsin in levels of the pancreas, especially with respect to lipase and amylase. The enzyme pattern of the porcine pancreas, featuring high lipase and amylase levels, was found most similar to that of the human pancreatic juice. Lyophilized porcine pancreatin was found best for enzyme substitution therapy in maldigestion syndrome. The porcine exocrine pancreas enzymes were also similar to the human pancreatic enzymes in terms of their molecular properties (molecular weight, isoelectric point, amino acid composition, and trypsin inhibition by Trasylol, Ovumucoid, and Kunitz pancreas trypsin inhibitor).

4407 IMMUNOCHEMICAL QUANTITATION OF PANCREATIC ENDOPEPTIDASES IN THE INTESTINAL CONTENTS OF GERMFREE AND CONVENTIONAL RATS. (Eng.) Genell, S.; Gustafsson, B. E.; Ohlsson, K. (Malmo General Hosp., S-214 01 Malmo, Sweden). *Scand. J. Gastroenterol.* 12(7):811-820; 1977.

Immunochemical techniques were developed and applied to study the fate of pancreatic endopeptidases in the intestinal canal of conventional and germfree Swedish AGUS-strain rats. Two electrophoretically distinct trypsins and chymotrypsins and an elastase were isolated from Sprague-Dawley rat pancreatic juice and rabbit antisera against these enzymes used in the immunochemical studies. In both types of rat, an anionic trypsin and chymotrypsin were the most abundant and were found in higher concentrations in the distal (trypsin, ≈700 μg/g intestinal contents and ≈1,000 μg/g; chymotrypsin, ≈700 and ≈1,800 μg/g for germfree and conventional rats, resp.) than the proximal small intestine (trypsin, ≈200 μg/g and chymotrypsin, ≈450 μg/g for both conventional and germfree rats). The cecal and fecal concentrations of anionic trypsin were markedly higher in the germfree (≈400 and ≈500 μg/g, resp.) than the conventional rat (<100 μg/g for both). Chymotrypsin was not detected in the large intestine of either type of rat. Immunoreactive elastase concentrations were significantly higher in the distal small intestine than in the proximal small intestine in both conventional and germfree rats. In germfree rats, immunoreactive elastase was higher in the cecum (≈2,000 μg/g intestinal contents) and feces (≈2,200 μg/g) than in the distal small intestine (≈1,400 μg/g). No elastase was demonstrated in the large intestine of conventional rats. The immunoreactive anionic trypsin and elastase in the fecal extracts were of the same molecular size as the native enzymes. These results suggest that the intestinal microflora is important in the degradation of elastase and trypsin, while nonbacterial mechanisms may play a similar role for chymotrypsin.

4408 EFFECT OF GLUCAGON ON CANINE EXOCRINE PANCREATIC SECRETION STIMULATED BY A TEST MEAL.

(Eng.) Singer, M. V.; Tiscornia, O. M.; Mendes de Oliveiro, J. P.; Demol, P.; Levesque, D.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM, 46, Chemin de la Gaye, 13009, Marseille, France). *Can. J. Physiol. Pharmacol.* 56(1):1-6; 1978.

The effect of glucagon on exocrine pancreatic secretion by a test meal was studied in three dogs with a chronic gastric fistula and a modified Thomas duodenal fistula. Glucagon was given by continuous i.v. infusion (5, 10, 15, or 30 μg/kg/hr) before and during a test meal. At each dose level, glucagon significantly reduced the water and electrolyte secretion of the pancreas ($p<0.05$ or $p<0.02$). At 15 and 30 μg/kg/hr, glucagon inhibited protein output (by 70% and 45%, resp.); this effect was absent at lower doses. These findings demonstrate a dose-dependent inhibition by glucagon of the pancreatic bicarbonate and protein response to a meal. Inhibition of bicarbonate output was more sensitive to glucagon than was protein output.

4409 A CONTROLLED TRIAL OF GLUCAGON IN ACUTE EXPERIMENTAL PANCREATITIS IN RATS.

(Eng.) Durr, H. K.; Weihe, W.; Bode, C.; Bode, J. C. (Medizinische Klinik der Philipps Universitat, Mannkopffstr. 1, D-3550 Marburg/Lahn, W. Germany). *Z. Gastroenterol.* 15(12):728-733; 1977.

The usefulness of glucagon in the treatment of acute pancreatitis was studied in 245 rats in which pancreatitis had been induced by retrograde instillation of Na-taurocholate into the pancreatic duct. The mortality rate in animals treated every 6 hr with glucagon (1 mg/kg) after the induction of pancreatitis was 50% as compared to 30% in the controls treated with 0.9% NaCl ($p<0.05$). The mortality rate in animals treated every 6 hr with the same dose of glucagon before the induction of pancreatitis was 36.5% as compared to 28% in the corresponding controls ($p>0.05$). Glucagon in lower doses (0.1-0.5 mg/kg/6 hr) did not alter mortality rates, as compared with animals treated with 0.9% NaCl. A nonlethal form of pancreatitis was induced in 26 rats by pancreatic duct ligation. The injection of glucagon (1 mg/kg) seemed to suppress amylase activities in blood for approximately 1 hr. However, 7 and 9 hr after the induction of pancreatitis, amylase activities were significantly higher in animals treated one or two times with glucagon as compared with those in untreated controls ($p<0.01$ or <0.001). It is concluded that glucagon in the high dose of 1-4 mg/kg/24 hr is useful in the treatment of acute pancreatitis in rats.

4410 FAT NECROSIS--A CAUSE OF PANCREATIC PARENCHYMAL NECROSIS?

(Eng.) Schmidt, H.; Lankisch, P. G. (Medizinische Klinik II, Schwalbacher Str. 62, D-6200 Wiesbaden, W. Germany). *Digestion* 17(1):84-91; 1978.

The pancreatic duct or the interstitial tissue of 34 male Sprague-Dawley rats were injected with 0.35 ml of a triglyceride or a product of lipolysis, namely, oleic acid (13 animals), olive oil (9), mono-olein (6), or paraffin oil (6) to test the effects of substances that are released by necrotic fat cells on the pancreatic parenchyma. The animals were killed 6 or 24 hr later, and the pancreas was removed and fixed for histological examination. Acute pancreatic necrosis with severe edema resulted in 6 hr when oleic acid was injected into the pancreatic duct. Similar, but somewhat less pronounced alterations, were produced by olive oil treatment. After injection of oleic acid into the pancreatic interstitial tissue, coagulation-type necrosis of acinar tissue developed after 6 hr adjacent to these droplets, and within 24 hr the necroses had extended into the acinar parenchyma. Again, olive oil treatment produced a similar result of lesser extent. Mono-olein or paraffin oil caused no histological alterations of acinar cells. It is concluded that the olive oil-induced pancreatic necrosis results from the detergent effect of fatty acids, which are locally accumulated during lipolysis of injected triglycerides by pancreatic lipase, and that may destroy cellular membranes by their high surface activity. The fatty acids split off in fat necrosis during acute pancreatitis may also damage adjacent pancreatic acinar tissue.

4411 REGULATION OF RAT EXOCRINE PANCREATIC SECRETION BY BILE [Abstract].

SECRETION AND METABOLISM

Hepatobiliary Tract

4417 EVALUATION OF LIVER FUNCTION BY INDOCYANINE GREEN (UJOVIRIDIN®) DURING NORMAL PREGNANCY, DELIVERY AND PUERPERIUM. (Ger.) Rudolf, H.; Goretzlehner, G.; Brugmann, E.; Towe, J.; Rudolf, K. (Klinik fur Innere Medizin, Ernst-Heydemann-Strasse, DDR-25, Rostock 1, E. Germany). *Zentralbl. Gynaekol.* 99(25):1548-1553; 1977.

Liver function was studied by the indocyanine green test (0.5 mg/kg i.v. in the form of bolus) during normal pregnancy, delivery, and *post partum* in 168 normal primigravidas and multigravidas and 18 normal nonpregnant women. None of the subjects had hepatopathy or cardiopathy. There was no significant difference in indocyanine green excretion between the control group (indocyanine half-life=3.64 min) and the pregnant women (3.77 min during the 8th week of pregnancy and 3.99 min during the 36th week). The half-life period increased during delivery (7.02 min), but it was normal again during the puerperium (3.92 min on the second day *post partum*). No placental transfer of the dye was demonstrable. The increase in the half-life during delivery is due to the physiological alterations of pregnancy. Indocyanine green is recommended instead of BSP for the estimation of the excretory function of the liver during pregnancy and puerperium.

4418 STUDIES USING SEDIMENTATION VELOCITY ON HETEROGENEITY OF SIZE AND FUNCTION OF HEPATOCYTES FROM MATURE MALE RATS. (Eng.) Sweeney, G. D.; Garfield, R. E.; Jones, K. G.; Latham, A. N. (McMaster Univ. Medical Center, 1200 Main St. West, Hamilton, Ontario L8S 4J9, Canada). *J. Lab. Clin. Med.* 91(3):432-443; 1978.

Methods to separate liver cells on the basis of size were developed to explore, using isolated cells, possible bases for selective centrilobular damage in liver damage by toxic substances. Hepatocytes were isolated from livers of fasted mature male Wistar rats after collagenase digestion. Examination of the size profile of these cells showed a modal peak ($3,979 \pm 277\ \mu m^3$, n=3) with significant skewing to the right. Sedimentation velocity analysis (SVA) permitted this hepatocyte suspension to be resolved into 12 fractions sedimenting at 97 to 25 mm/hr. Graphic representation of cell counts and cell volumes in fractions 1 to 12 recreated the cell size profile of the cell suspension prior to analysis. Mean volumes of cells in fractions 1 to 12 ranged from $10,920\ \mu m^3$ (fraction 1) to $2,320\ \mu m^3$ (fraction 12). Approximately one-fifth of recovered cells were found in fraction 9 (volume=$4,066\ \mu m^3$). Micromethods were developed to examine cytochrome P-450 content and aryl hydrocarbon hydroxylase (AHH) activity in fractionated cells. Analyses were conducted on paired fractions and expressed as a ratio of P-450 content per cell in the separated fractions to P-450 content per cell in the unseparated hepatocyte suspension. AHH was expressed similarly. Roughly sixfold greater P-450 content was found in fractions 1 + 2 than in fractions 9 + 10. The range for AHH activity was approximately fourfold, whereas the volumes of the cells differed only by a factor of 2.5. Cell densities were computed from sedimentation velocities and measured cell volume in each of fractions 1 to 12. Results ranged from 1.08 to 1.12 g/cm^3 with evidence for a discontinuity in the density profile in the region of fractions 5 to 7. This was attributed to the existence of two discrete cell populations: larger lighter cells and smaller heavier cells. Limited morphologic studies were conducted in which "large cells" (fractions 1 to 5) and "small cells" (fractions 8 to 11) were pooled and examined by electron microscopy. Cell detail was well preserved, difference in cell size was evident, and obviously binucleate cells were found only among the large cells. This work demonstrates significant heterogeneity among populations of hepatocytes and suggests that the larger cells have significantly greater activity of mixed function oxygenase systems. Sedimentation velocity-volume characteristics suggest the existence of two cell populations.

4419 EFFECTS OF PHENOBARBITAL AND 3-METHYLCHOLANTHRENE PRETREATMENT ON SIZE, SEDIMENTATION VELOCITY, AND MIXED FUNCTION OXYGENASE ACTIVITY OF RAT HEPATOCYTES. (Eng.) Sweeney, G. D.; Jones, K. G.; Krestynski, F. (McMaster Univ. Medical Center, 1200 Main St. West, Hamilton, Ontario L8S 4J9, Canada). *J. Lab. Clin. Med.* 91(3):444-454; 1978.

Sedimentation velocity analysis (SVA) was used to separate liver cells from rats pretreated for 3 days with phenobarbital (PB, 40 mg/kg, i.p., b.i.d.) or 3-methylcholanthrene (3-MC, 50 mg/kg as a single injection). Twelve fractions of cells were collected with sedimentation velocities (Vs) ranging from 97 mm/hr (fraction 1) to 25 mm/hr (fraction 12). PB caused the average volume of the largest cells recovered (fraction 1) to increase to 16,725 µm^3 from the 10,500 µm^3 previously reported in untreated animals. The number of cells recovered in the fast-sedimenting fractions (1-6) also increased in volume, but there was only a small rise in the average modal volume of hepatocytes determined prior to SVA. In cell suspensions analyzed after PB treatment, no evidence was found for a discontinuity in the distribution of density-volume characteristics. Prior to sedimentation analysis, hepatocyte suspensions from rats treated with PB contained an increased amount of cytochrome P-450. The average ratio (n=4) of P-450 in separated to unseparated cells ranged from 2.75 (fractions 1 + 2) to 0.38 (fractions 11 + 12), giving a 6.8-fold range in quantity of cytochrome per cell. Over this range, cell volume increased 4.2-fold, indicating a gradient in P-450 concentration similar to that previously reported to exist in cells from untreated rat liver. The gradient for aryl hydrocarbon hydroxylase (AHH) activity was 6.7-fold, suggesting that the activity of mixed function oxygenases (MFOs) paralleled the increase in cytochrome concentration. 3-MC pretreatment caused no significant increase in either size or number of cells in the fast-sedimenting fractions, but the discontinuity in density-volume characteristics that distinguished fast- and slow-sedimenting cells of untreated rats became marked. Furthermore, both the size and number of cells recovered in fractions 7 to 11 (that include the modal peak volume of unseparated hepatocytes) were increased. The gradient of P-450 (or P_1-450) was less steep in 3-MC-treated cells, with pooled fractions 1 and 2 containing an average of 4.62 times as much cytochrome as fractions 11 and 12. The gradient for AHH concentration was 4.29 times greater. The range of cell volume was 3.3-fold from fractions 1 + 2 to fractions 11 + 12. Additional experiments were performed to determine whether P-450, AHH, or NADPH cytochrome c reductase exhibited differences in activity or concentration per unit of cell volume between cells on either side of fraction 7 where discontinuity had been noted. Each variable was expressed per unit of cell volume in fractions 5 and 9; ratios were compared but were indistinguishable from unity. It is concluded that induction of MFO activity had occurred equally in both populations of cells. Densities were calculated from Vs and cell volume. Noticeable loss of density followed PB treatment in cells of all sizes. 3-MC had less of an effect on density but enhanced the increment in density observed at fraction 7, which corresponds to the division between cells with distinct sedimentation characteristics. These studies suggest that the enhancement by PB and 3-MC of different patterns of hepatic MFO activity are associated with different patterns of growth and development of the parenchymal cells during the 3-day treatment periods.

4420 HEPATIC CLEARANCE OF ENDOTOXINS: DIFFERENCES IN ARTERIAL AND PORTAL VENOUS INFUSION. (Eng.) Wolter, J.; Liehr, H.; Grun, M. (Dept. Surgery, Univ. Wuerzburg, W. Germany). *J. Reticuloendothel. Soc.* 23(2):145-152; 1978.

Studies were undertaken to determine whether there is a difference in the clearance of a fixed dose (0.16 mg/kg) of endotoxins by hepatic Kupffer cells when it is administered to minipigs via the hepatic artery or the portal vein. After arterial infusion, 11.4 µg of endotoxin per kg of body weight were extracted by the liver from the hepatic arterial blood before detectable amounts of endotoxin occurred in the hepatic venous blood in contrast to 57.0 µg/kg when administration was by portal venous infusion. This difference is thought to be due to at least two factors: (a) blood stream velocity within the liver (as measured by indocyanine green transit times), which was more rapid via the arterial route (3.6 ± 0.2 sec) than via the portal venous route (8.3 ± 0.3 sec) and (b) a shunting of blood flow due to portal hepatic venous and hepatic arterial venous intrahepatic shunts. Since such hemodynamic alterations are present in liver cirrhosis they may be the cause of the frequently observed systemic endotoxemia. These data indicate that endotoxin clearance is less efficient in the hepatic arterial blood system than in the hepatic portal venous system.

4421 BILE SECRETION AND LIVER CELL HETEROGENEITY IN THE RAT. (Eng.) Gumucio, J.

J.; Balabaud, C.; Miller, D. L.; DeMason, L. J.; Appelman, H. D.; Stoecker, T. J.; *et al.* (Univ. Michigan Medical Sch., Ann Arbor, MI 48109). *J. Lab. Clin. Med.* 91(2):350-362; 1978.

The contribution of hepatocytes of different acinar zones to bile salt transport and to the secretion of the bile salt-nonindependent fraction of canalicular water (BSNDF) was studied in female Sprague-Dawley rats. Changes in the removal of ^{14}C-taurocholate from blood, in the biliary secretion of taurocholate, and in canalicular flow were determined after damage of the periportal (acinar zone 1) or centrilobular (acinar zone 3) areas by allyl alcohol (6.2 mmol/kg) or bromobenzene (3.8 mmol/kg), resp. The extent of cell necrosis was quantitated by light microscopy, and the quality of the intracellular damage was assessed by electron microscopy. After either periportal or centrilobular damage, surviving cells responded to an i.v. infusion of taurocholate (300 nmol/min/100 g) by secreting bile salts into bile at a rate similar to controls. However, following the administration of ^{14}C-taurocholate at a high concentration (15 nmol/100 g) and as a single bolus, the rate of removal of this isotope from blood was slower than in controls. Both experiments suggest that periportal and centrilobular hepatocytes have the capability for bile salt transport. Consequently, since the concentration of bile salts in sinusoidal blood at each zone determines the relative contribution of hepatocytes to bile salt transport, periportal cells probably transport the largest amount of bile salts reaching the acinus. Canalicular bile flow, on the other hand, decreased following centrilobular cell damage, and this was associated with a high concentration of bile salts in bile. This suggests that, at bile salt loads near physiological concentrations, the predominant contribution of centrilobular hepatocytes is to the secretion of the BSNDF.

4422 STUDY OF BILE ACIDS BIOSYNTHESIS IN RAT LIVER SLICES USING [1-^{14}C]ACETATE: RESULTS WITH RATS FED A BASAL DIET WITH OR WITHOUT CHOLESTYRAMINE SUPPLEMENTATION.

(Fre.) Grandgeorge, M.; Duperray, B.; Pacheco, H. (Institut National de Sciences Appliquees, 20, ave. Albert-Einstein, F 69621 Villeurbanne, France). *J. Pharmacol.* 8(3):297-314; 1977.

A method for the *in vitro* measurement of bile acid synthesis is presented and applied to the investigation of the biosynthesis of cholesterol, cholic acid (C), chenodeoxycholic acid (CDC), and fatty acids in rat liver slices from male Wistar rats incubated with the radioactive precursor 1-^{14}C-acetate for 75 min. Following incubation, the bile acids were extracted, methylated, separated by column chromatography, purified by thin-layer chromatography, and their radioactivity compared to that of the remaining free cholesterol. In 10 rats on the unsupplemented diet, the ratio of C+CDC: cholesterol was dependent on the 7-α-hydroxylase activity, while the ratio CDC:C varied inversely with 6-β-hydroxylase and 12-α-hydroxylase activity. When rats were given cholestyramine (192 mg Dowex resin in suspension/rat/day, by intragastric tube) for 10 days prior to sacrifice, the production of C increased by 184% and the level of C+CDC rose 68%. The ratio CDC:C dropped from 1.82 to 0.77. Incorporation of 1-^{14}C-acetate into fatty acids rose by 55%, but this rise was not significant because of the wide scattering of results. The incorporation of 1-^{14}C-acetate into cholesterol increased by 340% and the amount of free cholesterol in the liver rose by 15%. Serum and intestinal cholesterol were not significantly increased over controls. These results are consistent with an activation of 7-α-hydroxylase, 12-α-hydroxylase, and 6-β-hydroxylase activities by cholestyramine.

4423 PHYSIOLOGICAL FACTORS INFLUENCING SERUM BILE ACID LEVELS.

(Eng.) Ponz de Leon, M.; Murphy, G. M.; Dowling, R. H. (Guy's Hosp. Medical Sch., London, England). *Gut* 19(1):32-39; 1978.

The effects of fasting (prolongation of an overnight fast for a further 4 hr), feeding (the response to eating the three main "solid" meals of the day), and cholecystokinin (CCK)-induced gallbladder contraction (75-100 U of CCK given as a bolus i.v. injection) on serum individual bile acids were studied in five to eight healthy subjects. The serum conjugates of cholic and chenodeoxycholic acids were measured using sensitive specific radioimmunoassays. During fasting, there was no significant change in the levels of the individual serum bile acids (conjugates of cholate, 1.28 ± 0.19 μM; conjugates of chenodeoxycholate, 1.17 ± 0.17 M). After breakfast, the serum conjugates of cholate and chenodeoxycholate increased significantly, but thereafter the mean values remained high with less consistent responses to lunch and dinner. Some subjects showed a peak and trough response to all three meals, while others showed a plateau response throughout the day. After breakfast, the serum chenodeoxycholate conjugates increased more rapidly (peak at 60 min, when the concentration reached 2.07 ± 0.30 μM) and to a greater extent than the conjugates of cholate (peak at 90 min, 1.50 ± 0.24 μM). A similar pattern of results was seen after i.v. CCK, suggesting either preferential jejunal absorption of chenodeoxycholate conjugates and/or preferential hepatic clearance of cholate conjugates. These results provide essential background data for future studies of serum individual bile acids in intestinal and hepatic disease.

4424 URSODEOXYCHOLATE--IN VITRO CHOLESTEROL SOLUBILITY AND CHANGES OF COMPOSITION OF HUMAN GALLBLADDER-BILE AFTER ORAL TREATMENT.

(Eng.) Igimi, H.; Tamesue, N.; Ikejiri, Y.; Shimura, H. (First Dept. Surgery, Fukuoka Univ., Fukuoka, 814, Japan). *Life Sci.* 21(9):1373-1379; 1977.

To investigate the usefulness of ursodeoxycholic acid (UDCA) for gallstone dissolution, the *in vitro* solubility of cholesterol in bile salt solutions with and without lecithin and the composition of gallbladder bile in 25 patients after treatment with UDCA were examined. Solutions of the Na salts of

UDCA, chenodeoxycholic acid (CDCA), and cholic acid (CA) were prepared at 100, 50, and 25 mM concentrations, and 50 and 100 mM solutions of equimolar amounts of NaUDCA and NaCDCA or of NaCA and NaUDCA were also made. Lecithin at one-fourth of the given salt concentration was added to these solutions for some experiments. Cholesterol solubility increased proportional to the salt concentration. NaCDCA had the best solubilizing properties and NaUDCA the worst (233.7 ± 2.0, 102.4 ± 1.8, and 42.3 ± 1.1 mg/dl compared to 2.1 ± 0.1, 1.5 ± 0.1, and trace mg/dl at 100, 50, and 25 mM, resp.). All other bile salt solutions gave intermediate results. The addition of lecithin to the bile salt solutions increased cholesterol solubilization to a large extent, but did not change the efficacy relationships among the bile salt solutions. Five groups of five patients each, all with diseases not in the hepatobiliary tract, were given daily p.o. doses of 0, 150, 300, 600, or 1,200 mg NaUDCA for 1 week. The content of total bile acids, phospholipids, and cholesterol as well as of the single bile acid UDCA were increased. At the 300 and 600 mg doses of UDCA, the mole percentage of total bile acids was increased ($p<0.01$), and that of phospholipids and of cholesterol was decreased ($p<0.01$ and $p<0.05$ or $p<0.01$, resp.). The 1,200-mg/day dose had a significant effect only on the cholesterol level, decreasing it ($p<0.01$). The UDCA treatment does not appear to influence the metabolism of the other bile acids as does treatment with CDCA. Oral treatment with UDCA should be inferior to CDCA treatment for the dissolution of gallstones.

4425 REMOVAL OF PLASMA BILIRUBIN BY HEMOPERFUSION IN DOGS.

(Eng.) Lopukhin, U. M.; Molodenkev, M. N.; Leykin, U. A.; Gorchakov, V. D.; Evseev, N. G.; Ryabov, A. V. (2nd Moscow Medical Inst., Moscow Inst. Chemical Technology, Moscow, USSR). *Am. J. Gastroenterol.* 68(4):345-353; 1977.
